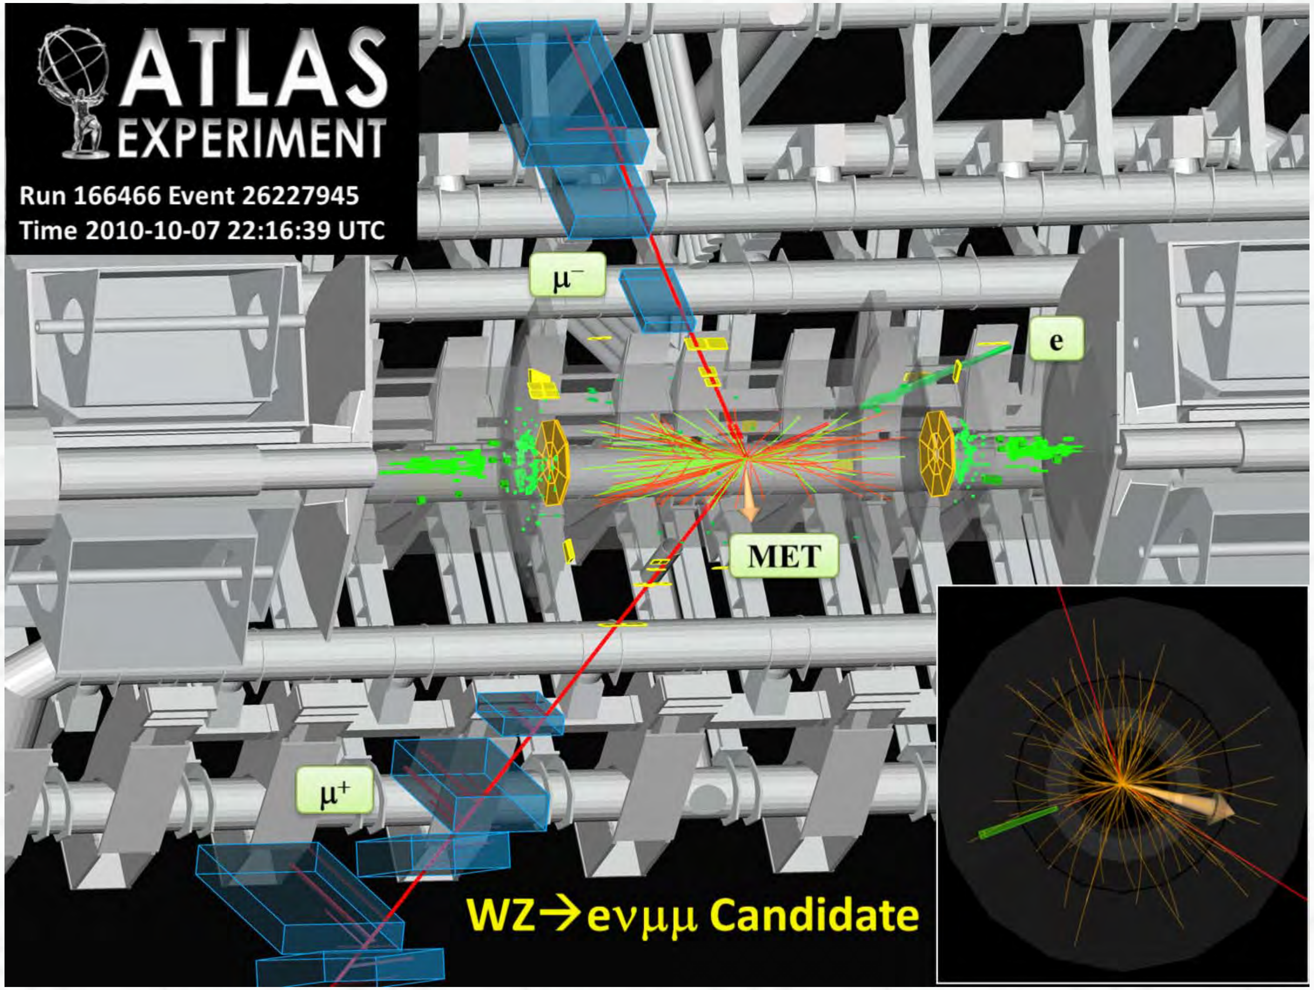
Physics at Hadron Colliders



1. Introduction, Particle Accelerators

1.1 Why hadron collider?

1.2 Principles of particle accelerators

1.3 The *Large Hadron Collider* (LHC) at CERN

1.4 The Tevatron Collider at Fermilab

1.1 Why Hadron Collider?

Key questions investigated in particle physics:

(i) Structure of matter; fundamental constituents $\lambda = h / p$

(ii) Search for new particles, new types of matter $E = m c^2$

For the investigation of both questions, high energies and thereby particle accelerators are needed

High Energy Particle Accelerators (last 25 years):

Accelerator	type, laboratory	energy $\sqrt{s}$	years of operation
LEP-I	e^+e^- collider, CERN	91 GeV	1989 - 1994
LEP-II	e^+e^- collider, CERN	209 GeV	1995 - 2000
HERA-I	ep collider, DESY	27 + 800 GeV	1992 - 2000
HERA-II	ep collider, DESY	27 + 920 GeV	2002 - 2007
TeVatron Run I	ppbar collider, Fermilab	1.8 TeV	1987 - 1996
TeVatron Run II	ppbar collider, Fermilab	1.96 TeV	2002 - 2011
LHC, Run 1	pp collider, CERN	7 TeV	2010- 2012
LHC, Run 2	pp collider, CERN	13 - 14 TeV	2015- …….

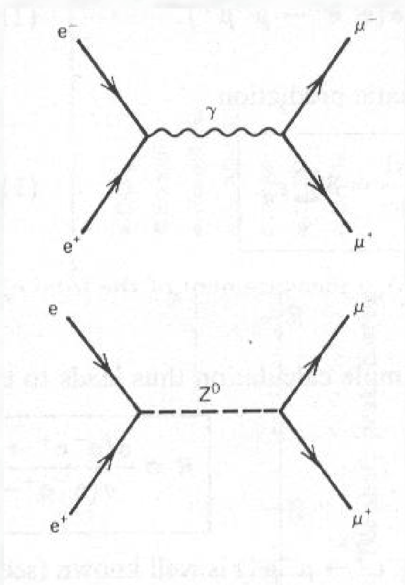
Important parameters of accelerators:

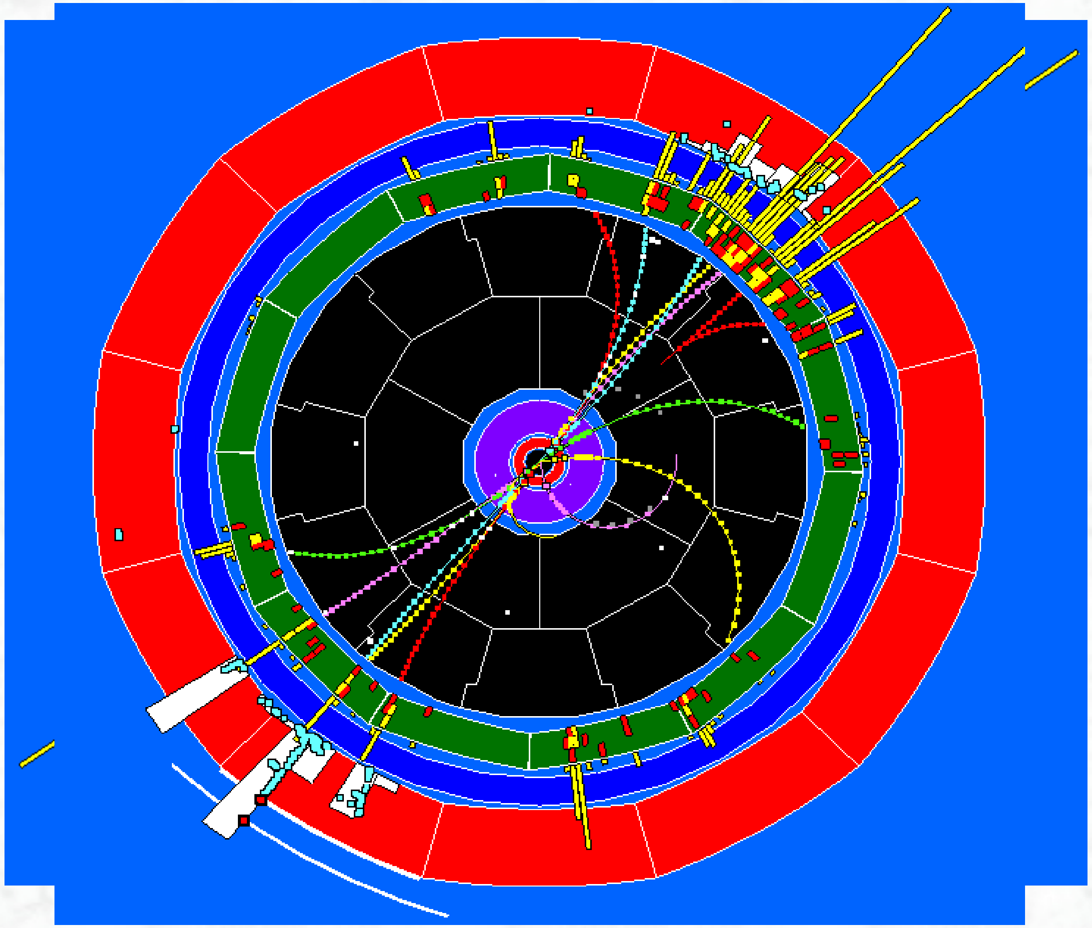
- Beam energy,   centre-of-mass energy $\sqrt{s}$
- Type of particles (ee, ep, or pp) and form of accelerator
  (circular or linear accelerator)
- Luminosity L, or integrated Luminosity
  (measured in units of cm^{-2} s^{-1})

Why a hadron collider ?

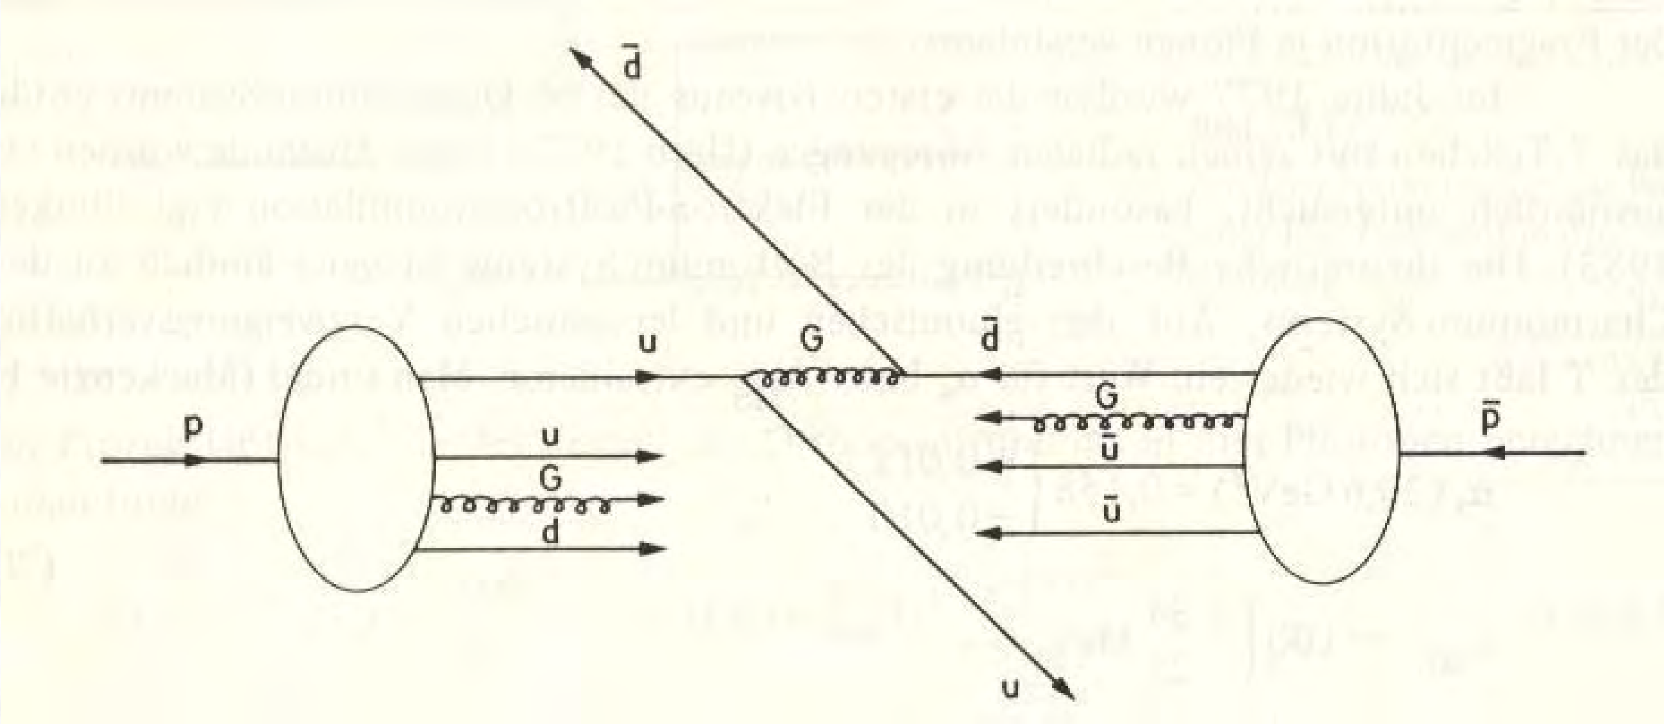
e^+e^- colliders are excellent machines for precision physics !!

- $e^+ e^-$ are point-like particles, no substructure → clean events
- complete annihilation, centre-of-mass system, kinematic fixed

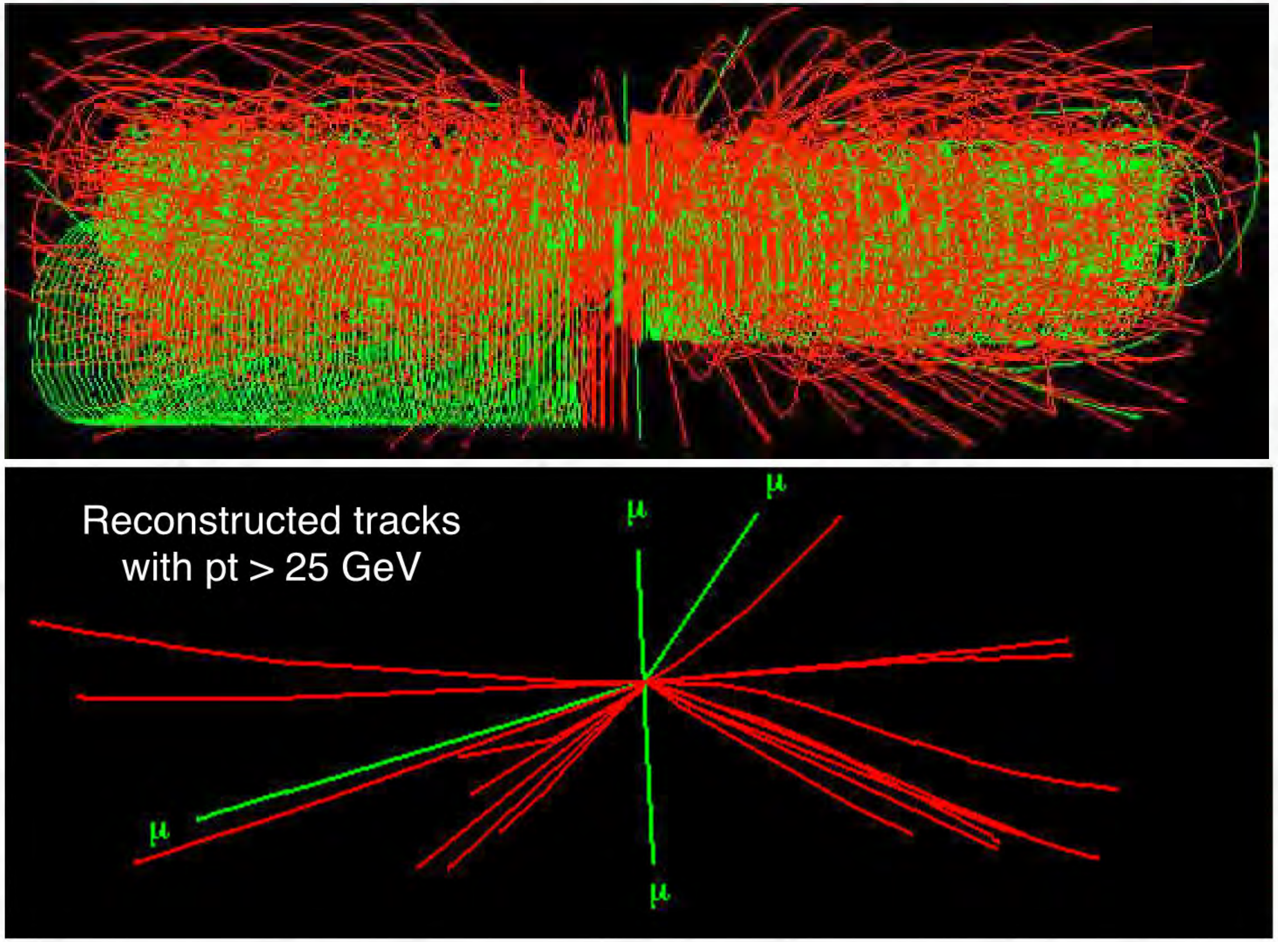




Proton-proton collisions are more complex



Simulation of a pp collision at the LHC: $\sqrt{s}$ = 14 TeV, L = 10^{34} cm^{-2} s^{-1}



Reconstruction of particles with high transverse momenta reduces the number of particles drastically
(interesting objects kept, background from soft inelastic pp collisions rejected)

Main drawbacks of e^+e^- circular accelerators:

1. Energy loss due to synchrotron radiation
   (basic electrodynamics: accelerated charges radiate,
   x-ray production via bremsstrahlung, synchrotron radiation……)

   - Radiated power (synchrotron radiation):
     Ring with radius R and energy E

$$P = \frac{2\, e^2\, c}{3\, R^2} \left(\frac{E}{mc^2} \right)^4$$

   - Energy loss per turn:
     (2 GeV at LEP-II)

$$-\Delta E \approx \frac{4\, \pi\, e^2}{3\, R} \left(\frac{E}{mc^2} \right)^4$$

   - Ratio of the energy loss between protons and
     electrons:

$$\frac{\Delta E(e)}{\Delta E(p)} = \left(\frac{m_p}{m_e} \right)^4 \sim 10^{13}$$

Future accelerators:

- pp ring accelerators (LHC, using existing LEP tunnel)
- Or e^+e^- linear accelerators, International Linear Collider ILC or CLIC (under study / planning)

Limiting factors:

$e^+ e^-$ accelerators:

- -Energy loss is circular rings
- -Acceleration gradient in linear accelerators
  (ILC design, 40 MV / m)
- Fixed centre-of-mass energy….

pp accelerators:

-More complex interactions due to proton substructure
-Only part of the pp centre-of-mass energy available in the hard scattering process (see later)
However: higher mass values can be reached with longer running times

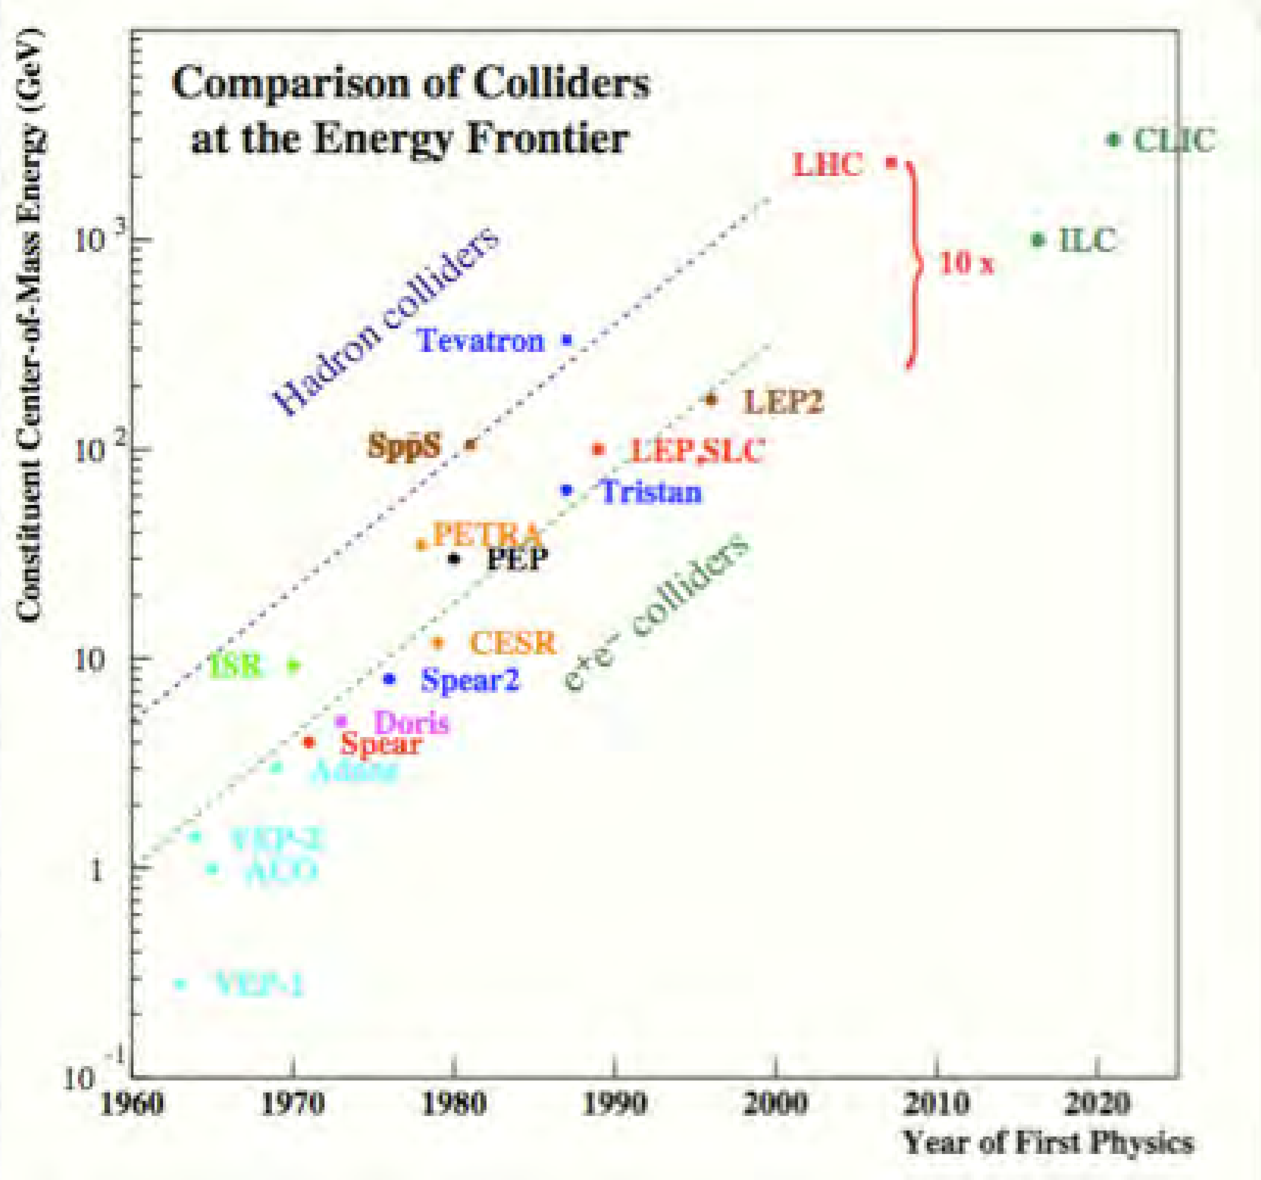
-Limiting factor: Magnetic field in bending magnets
(8.3 T in LHC magnets)

Accelerators at the energy frontier

Livingston plot

Exponential growth of
$\sqrt{s}$ with time
(at least in the past)

Factor 4 every 10 years

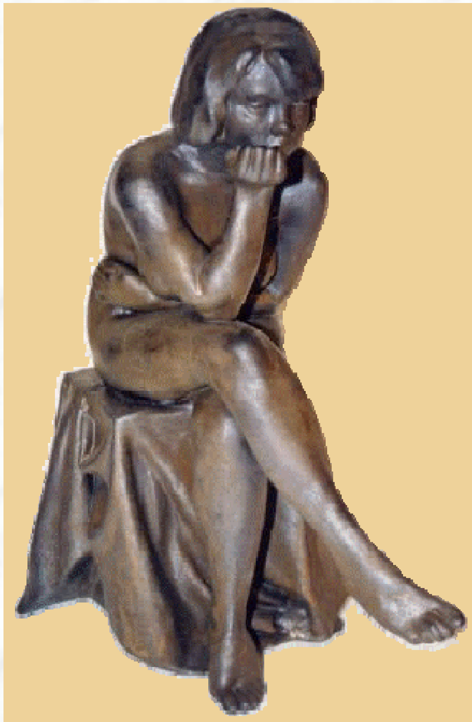


pp: discovery machines
(W/Z, top, Higgs,….)

e^+e^-: precision
(LEP, QCD and el.weak)

Both required !

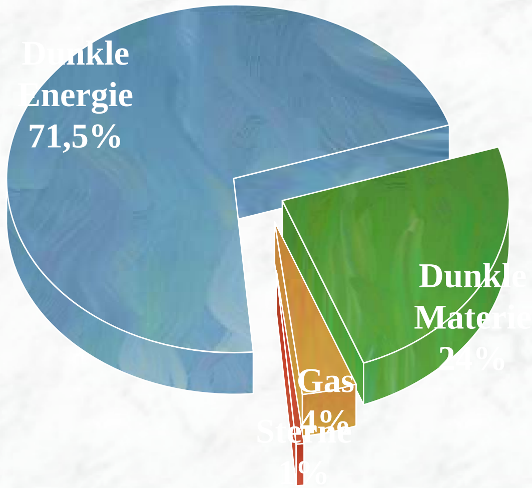
Today's open questions in particle physics



Key questions of particle physics

1. Mass

What is the origin of mass?
Does the Higgs particle exist?
Much progress: discovery of a Higgs boson at the LHC

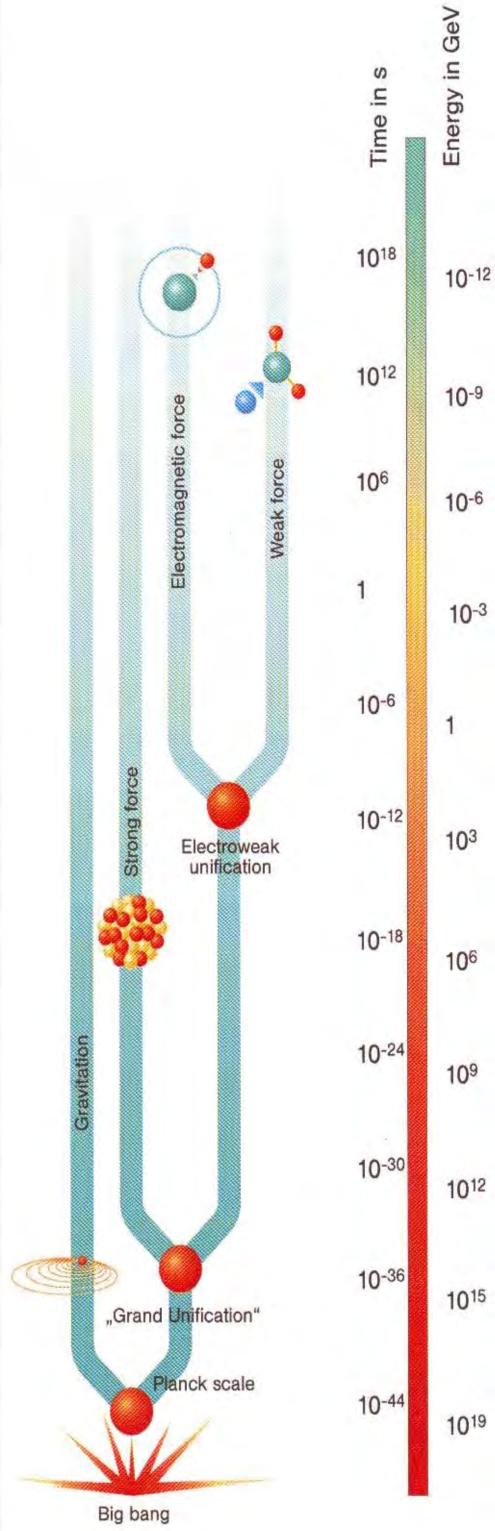


2. Unification

- Can the interactions be unified?
- Are there new types of matter, e.g. supersymmetric particles ?
  Are they responsible for the Dark Matter in the universe?

3. Flavour

- Why are there three generations of particles?
- What is the origin of the matter-antimatter asymmetry (Origin of CP violation)



Answers to some of these questions are expected on the TeV energy scale, i.e. at the LHC

The role of the LHC

1. Explore the TeV mass scale

- What is the origin of the electroweak symmetry breaking ?
  After Higgs boson discovery: is it the Standard Model Higgs boson?
  What are its properties?

- The search for “low energy” supersymmetry
  Can a link between SUSY and dark matter be established?

- Other scenarios beyond the Standard Model
- …….

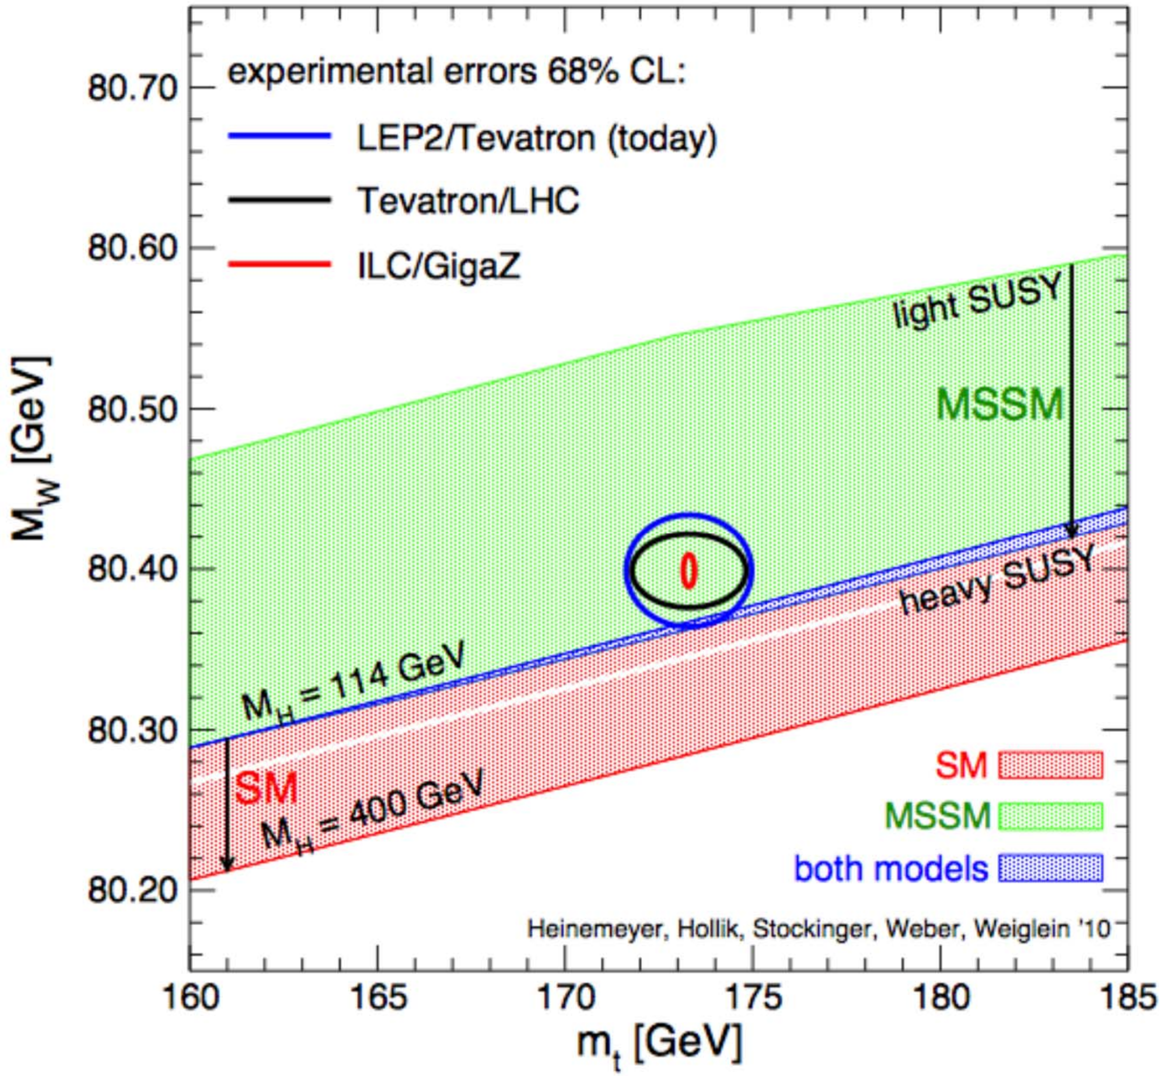
Look for the “expected”, but we need to be open for surprises

→ perform as many searches (inclusive, exclusive…) for as many final states as possible

2. Precise tests of the Standard Model

- There is much sensitivity to physics beyond the Standard Model in the precision area

- Many Standard Model measurements can be used to test and to tune the detector performance

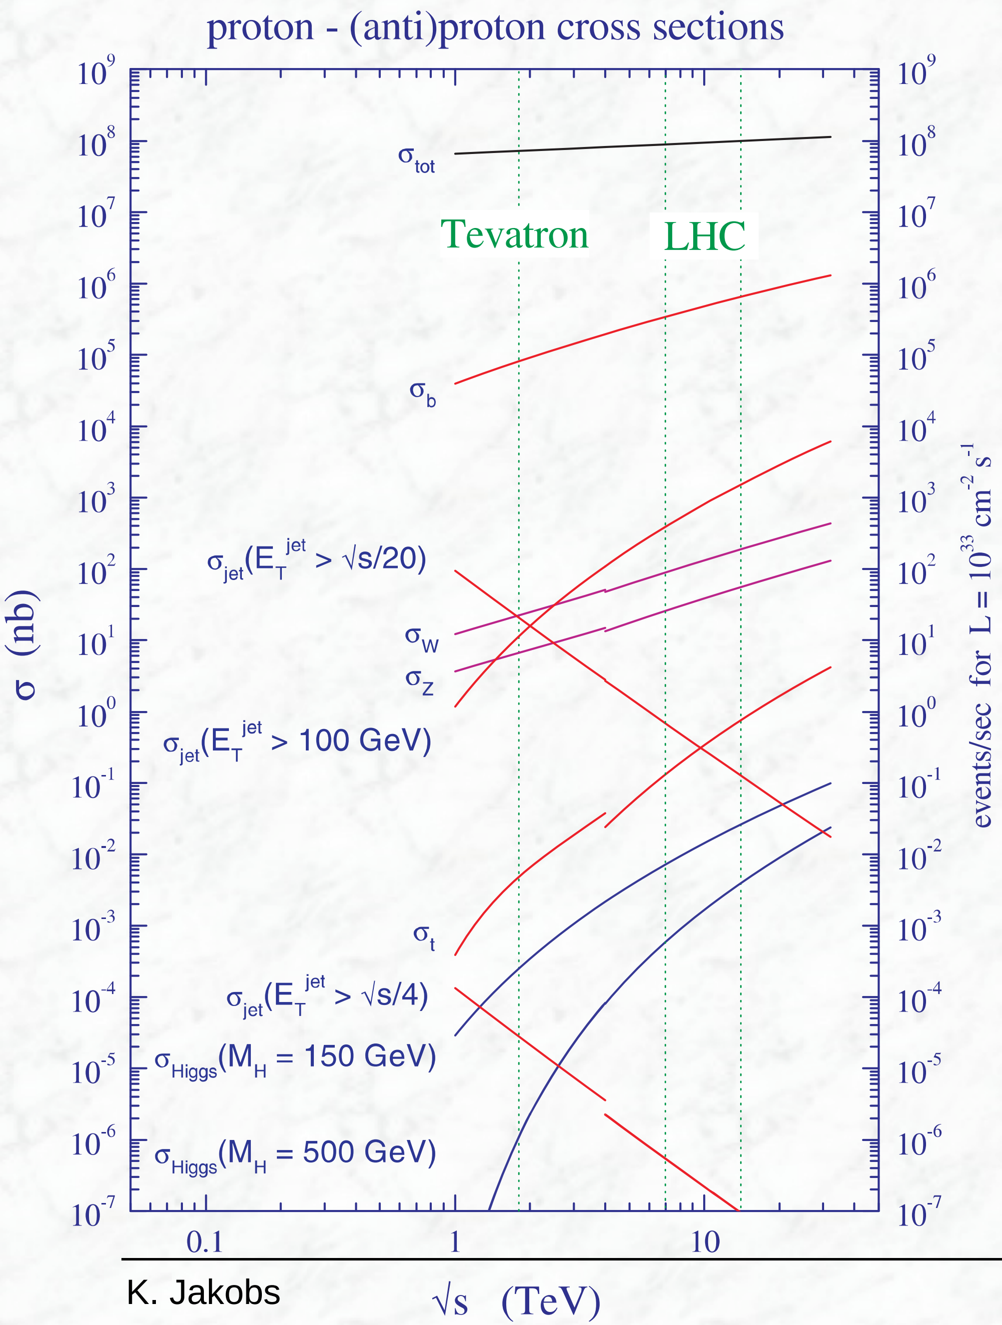


Predictions for future precision (including LHC), compared to the Standard Model and its Minimal Supersymmetric Extension (MSSM)

Ultimate test of the Standard Model: compare direct prediction of Higgs boson mass with direct observation many possible theoretical models exist

experimental guidance is needed

Production Rates and Cross Sections at the LHC



$$N = \sigma \cdot L$$

$$\left[\frac{1}{s}\right] = \left[cm^2 \cdot \frac{1}{cm^2 \cdot s}\right]$$

Rates for the design luminosity:
$\sqrt{s}$ = 7 TeV, L = 10^{33} cm^{-2} s^{-1}:

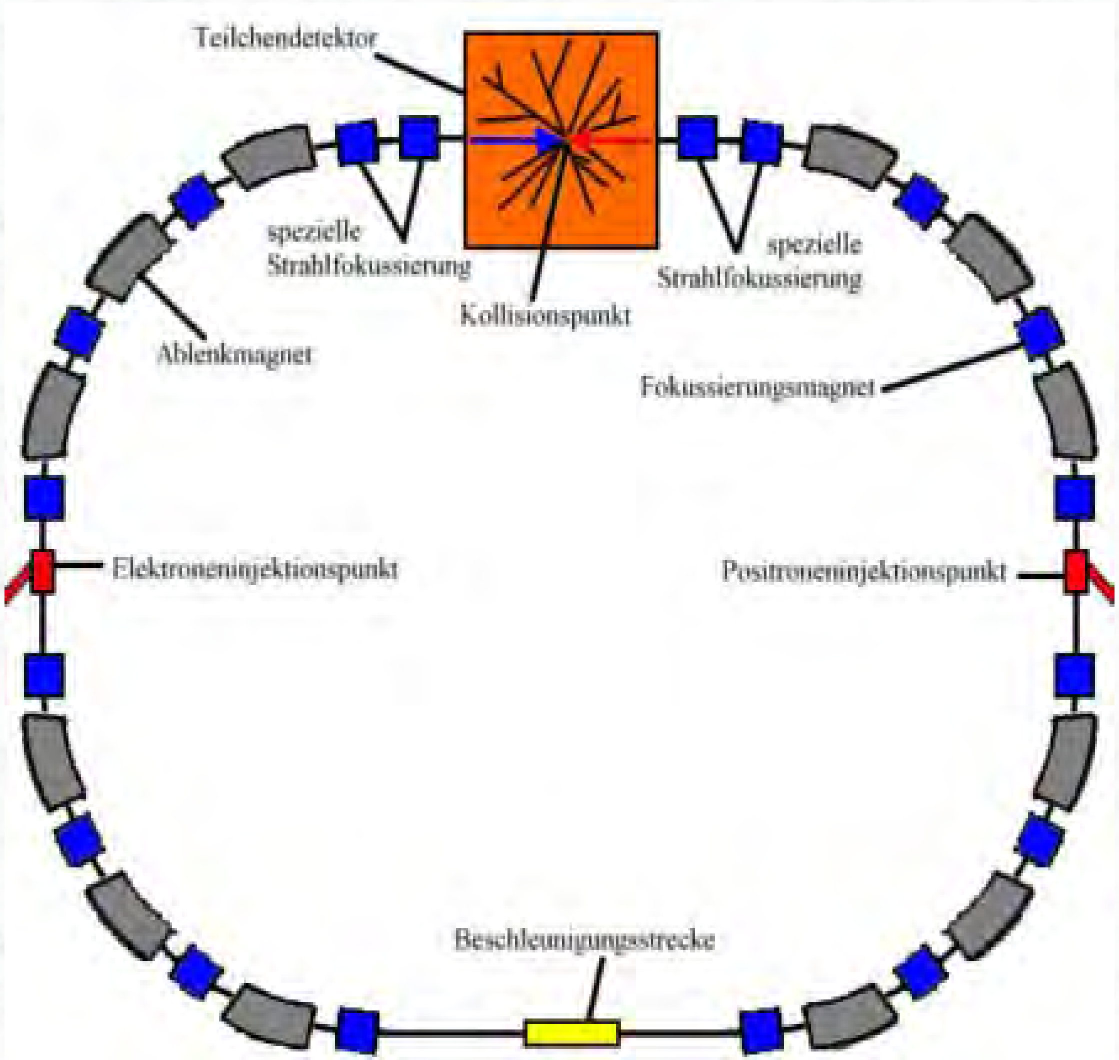
- Inelastic proton-proton collisions: 10^8 / s

- bb pairs $5 \; 10^5$ / s
- tt pairs 1 / s

- W → e ν 15 / s
- Z → e e 1.5 / s

- **Higgs (150 GeV) 0.02 / s**
- **Gluino, Squarks (1 TeV) 0.003 / s**

1.2 Principles of particle accelerators

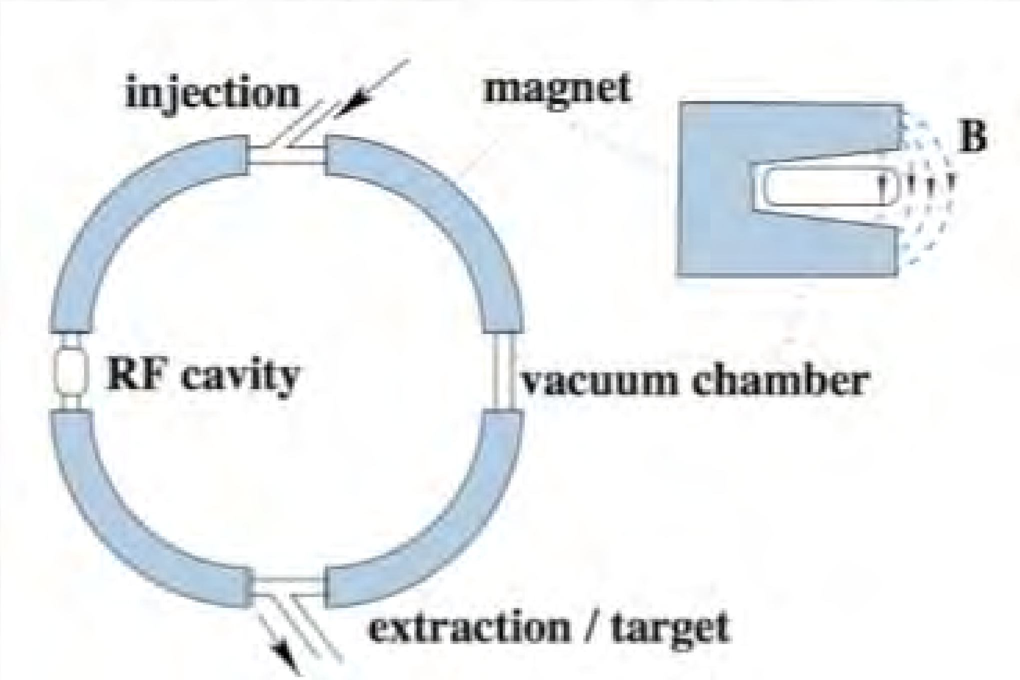


Circular accelerator principles

- Cyclotron: constant RF
  magnetic field radius ρ increases with energy
  used for smaller machines

- Synchrotron: ρ = const
  B increases with energy
  RF frequency adjusted slightly (β = 0.999 …..1.0)

Most High Energy accelerators and all CERN ring accelerators (PS, SPS, LEP, LHC) are of this type



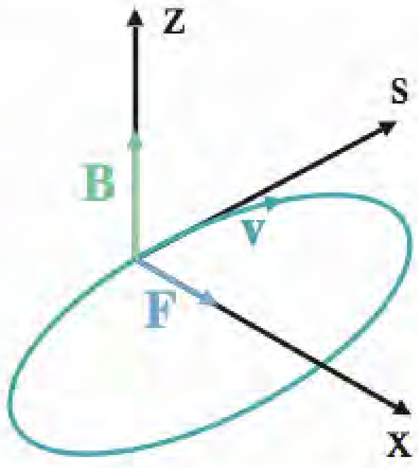
Basic parameters, Lorentz Force

$$\mathbf{F} = q\,(\mathbf{E} + \mathbf{v} \times \mathbf{B})$$

charge q, normally $q = e$; $q = Z\,e$ for ions

- Electric field **E** provides the acceleration or rather energy gain
- The magnetic field **B** keeps the particles on their path

Circular motion for
$\mathbf{E} = 0$
$\mathbf{v} \perp \mathbf{B}$



ρ is the radius of curvature for motion perpendicular to the static magnetic field. Often called
- gyromagnetic or Larmor radius in astroparticle physics
- bending radius for accelerators

$B\rho$ known as magnetic rigidity, units Tm

$$B = \frac{p}{q\,\rho}$$

for $q = e$ numerically

$B\,[\mathrm{T}] = p\,[\mathrm{GeV/c}]\quad 3.336\ \mathrm{m}/\rho$

high energy, $v = c$ "$p = E$"

$E < E_H = q\,B\,\rho$ Hillas criterion

LHC

- **Momentum $p = 7$ TeV/c**
- **LHC bending radius $\rho = 2804$ m**
- **Bending field B = 8.33 Tesla**
- **magnets at 1.9 K, super-fluid He**

Astroparticle

units $10^{-4}\,\mathrm{T} = 1\,\mathrm{Gauss}$; a.u. $= 1.5\times10^{11}$ m

Solar system $B = 10\,\mu\mathrm{G}$ $E = 5$ TeV $\rho = 11$ a.u.

Intergalactic $B = 1\,\mathrm{nG}$ $E = 5$ PeV (knee)

$\rho = 1.7\times10^{19}$ m (4 % of galaxy-radius)

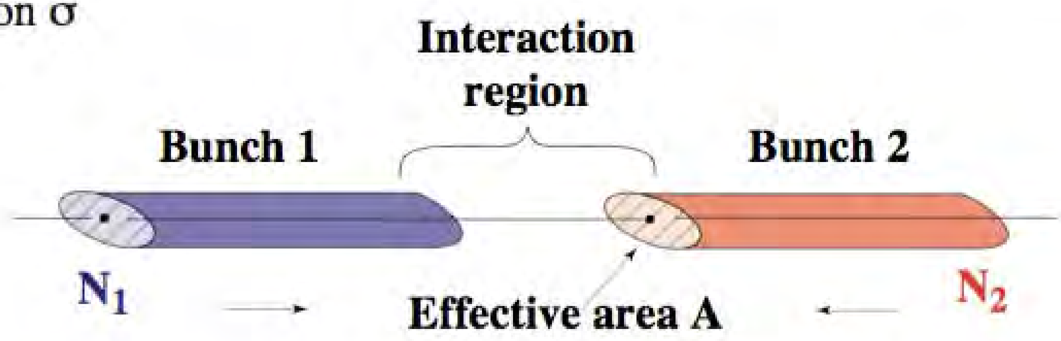
Luminosity and collision rates

Event rate for process with cross section σ

$$\dot{n} = \mathcal{L}\sigma$$

Luminosity from bunch crossings at frequency $f = f_{rev}\, n_b$

$$\mathcal{L} = \frac{N_1 N_2 f}{A}$$



for Gaussian bunches with rms sizes $\sigma_x\ \sigma_y$ $\quad \mathbf{A} = 4\,\pi\,\sigma_x\,\sigma_y$

High luminosity: Large number of particles (N_1, N_2)
Small beam dimensions (A) in the interaction point
Large f (large number of bunches,
→ small time difference between bunch crossings)

LHC: $N = 1.15\ 10^{11}$, $n_b = 2808$ (number of bunches)
bunch separation: 25 ns (corresponds to 7.5 m)
A: beams squeezed (using strong, large aperture quadrupoles close to the interaction region) from $\sigma = 0.2$ mm to 16 μm

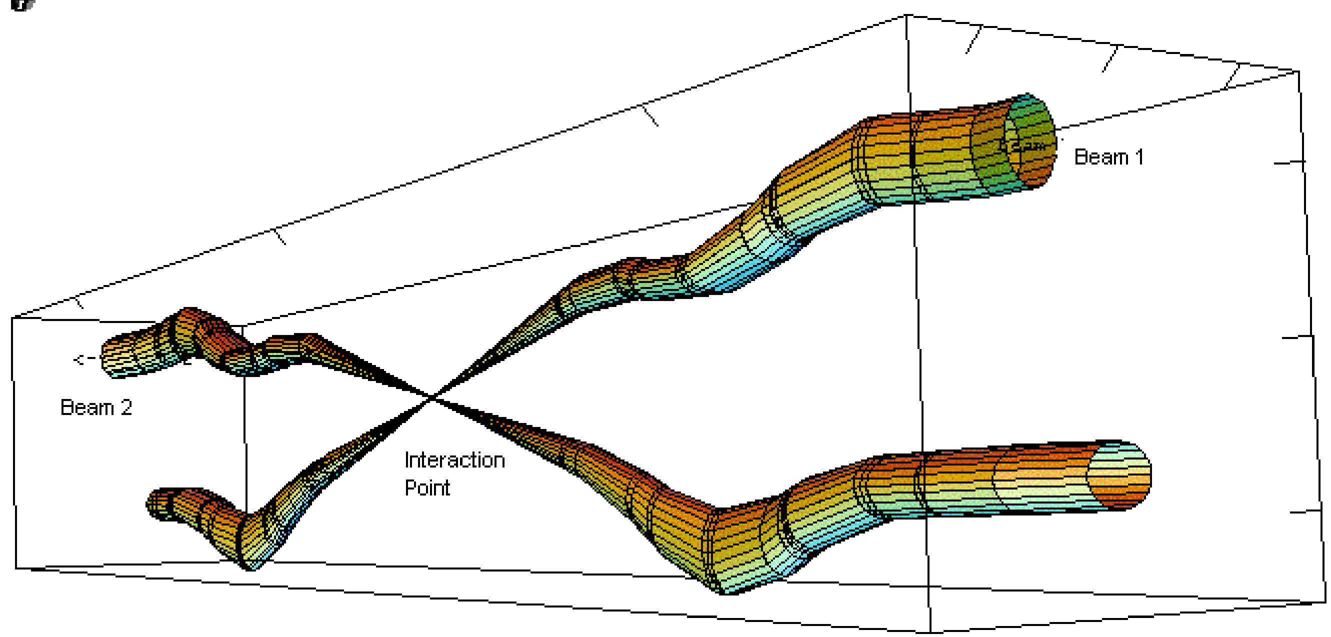
$$L = f\frac{N_1 \; N_2}{4\pi \; \sigma_x \sigma_y} = f\frac{N^2}{4\pi \; \sigma^2}$$

for $N = N_1 = N_2$ particles per bunch with transverse r.m.s. beam size $\sigma = \sigma_x = \sigma_y$ and frequency f

Accelerator physicist express this often using the transverse emittance ε and the β function:

$$L = f\frac{N_1 \; N_2}{4 \sqrt{\epsilon_x \beta_x^* \epsilon_y \beta_y^*}}$$

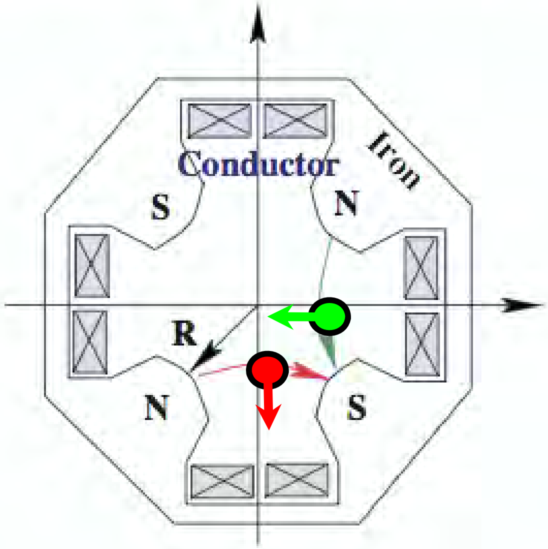
where $\epsilon = \pi\sigma^2/\beta$

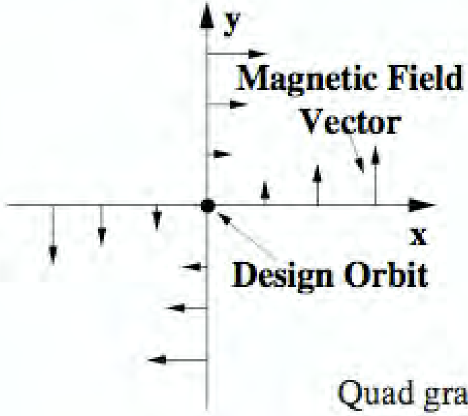


Relative beam sizes around IP1 (Atlas) in collision

Alternate gradient focusing

Quadrupole lens focusing in x, defocusing in y or vice versa





$B_x = k\,y$
$B_y = k\,x$
$B_z = 0$

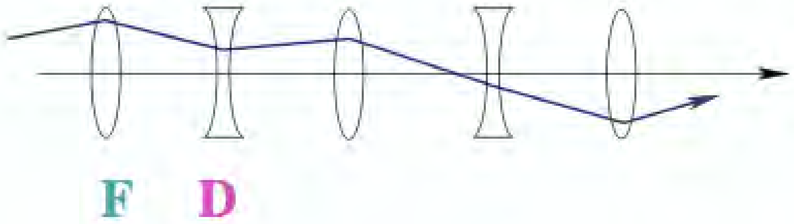
$\nabla \times B = 0$

Quad gradients in the LHC
$K = 1/B\varrho \;\; \partial B_y/\partial x \approx 200$ T/m

$\mathbf{F} = e\,(\mathbf{v} \times \mathbf{B})$
here
$\mathbf{F} = e\,(0, 0, v) \times (B_x, B_y, 0)$
$= e\,(-v\,B_y,\; +v\,B_x,\; 0)$

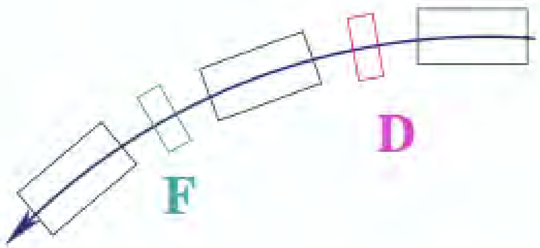
Combine F D
Defocusing when at small amplitude
Overall focusing

alternate gradient focusing



Normal (light) optics :
Focal length of two lenses at distance D
$1/f = 1/f_1 + 1/f_2 - D/f_1 f_2$
is overall focusing
with $1/f = D/f^2$
for $f = f_1 = -f_2$

together with bending magnets FODO lattice



N. C. Christofilos, unpublished manuscript in 1950 and patent
Courant, Snyder in 1952, Phys. Rev. 88, pp 1190 - 1196 + longer review in Annals of Physics 3 (1958)

Betatron motion

Equation of motion of particles in a ring (with bending fields) **and quadrupoles** (field gradients $\propto \partial B / \partial r$)

In both transverse planes, here written with x for x, y : $x' = dx(s)/ds$; $x'' = d^2x(s)/ds^2$

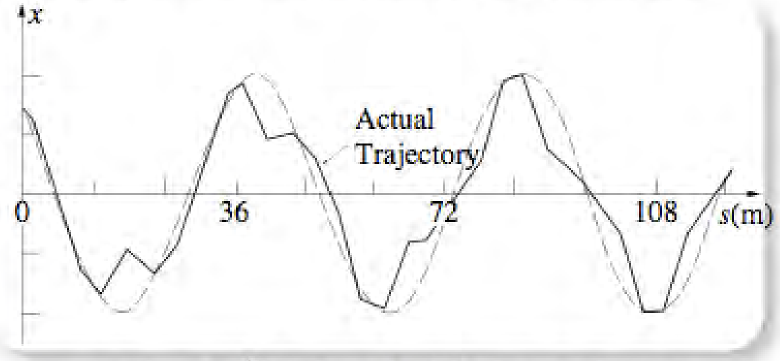
$x''(s) + k(s)\,x(s) = 0$ known as Hill's equation, derived in 1801 to describe planetary motion

Generalised oscillator equation with position dependent, periodic restoring force $k(L+s) = k(s)$ given by the quadrupole gradients (+ the small weakly focusing bending term in the ring plane)

Solution : $$x(s) = \sqrt{\epsilon\,\beta(s)}\,\cos(\mu(s) + \phi)$$

Phase advance $$\mu(s) = \int_0^s \frac{ds}{\beta(s)}$$

Tune # of betatron oscillations $$Q = \mu / 2\pi$$



motion $x/\sqrt{\beta}$ *plotted with phase advance normalised coordinates - becomes simple cos*

$\beta(s)$ **beta function**, describes the focusing properties of the magnetic lattice

ϵ invariant, together with $\beta(s)$ amplitude. "single particle emittance"

Motion conveniently described in phase space (x, x′) with local slopes or angles $x' = p_x / p$ and linear optics elements as matrices ; with simple case for M, applies for IP to IP

$$\begin{pmatrix} x(s) \\ x'(s) \end{pmatrix} = \mathbf{M} \begin{pmatrix} x(s_0) \\ x'(s_0) \end{pmatrix} \qquad \mathbf{M} = \begin{pmatrix} \cos 2\pi Q & \beta \sin 2\pi Q \\ -\frac{1}{\beta} \sin 2\pi Q & \cos 2\pi Q \end{pmatrix}$$

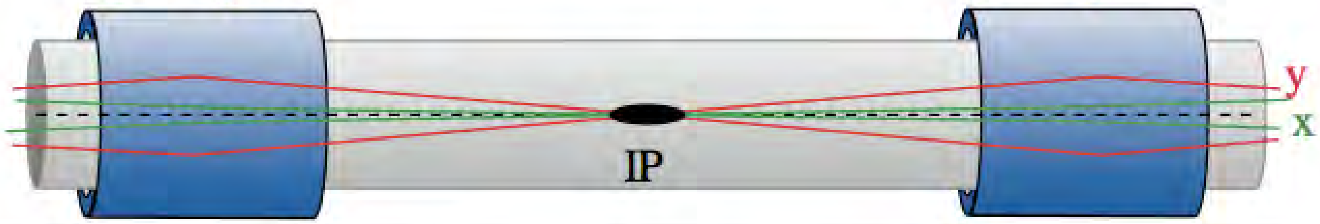
Transverse beam size and emittance

consider : beam of many particles on stable orbit and
simple case : dispersion and slope $\beta' = 0$ by default at IP - relevant for experiments

beam size, r.m.s.	$\sigma(s) = \sqrt{\varepsilon\beta(s)}$
beam divergence, r.m.s.	$\theta(s) = \sqrt{\varepsilon/\beta(s)}$
product	$\varepsilon = \sigma(s)\theta(s)$

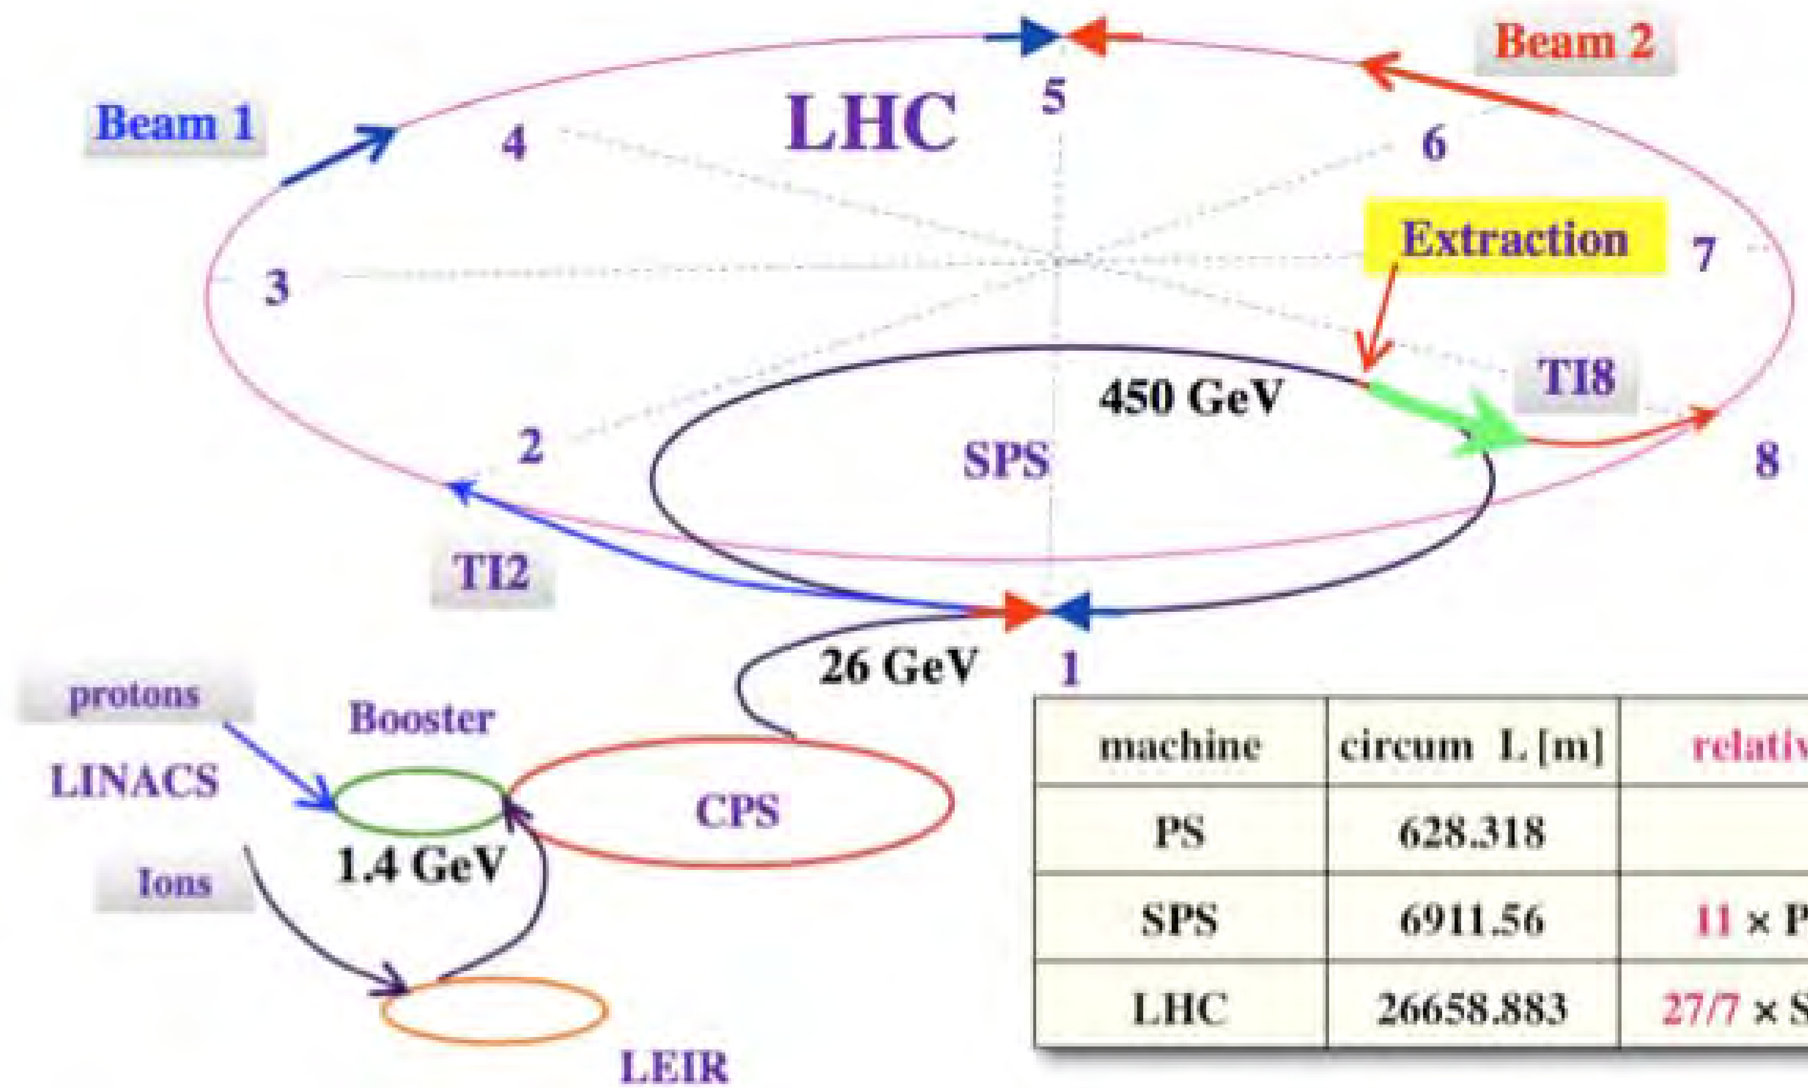
β - function : local machine quantity - focusing of lattice
Emittance ε : beam quantity - the average action
related to phase space density or kind of beam temperature
given by initial conditions (injected beam)
or equilibrium of quantum excitation and damping - 2nd lecture
in ideal machine : x, y, z motion uncoupled, 3 emittances ε_x, ε_y, ε_z

IP: squeeze β to a minimum, called β* ⇒ maximum of divergence, needs aperture



LHC $\varepsilon_N = \varepsilon\,\beta\gamma = 3.75$ µm, at top $E_b = 7$ TeV: $\varepsilon = 0.503$ nm, $\beta^* = 0.55$ m, $\sigma^* = 16.63$ µm, $\theta^* = 30$ µrad

The CERN accelerator complex: injectors and transfer



machine	circum L [m]	relative
PS	628.318

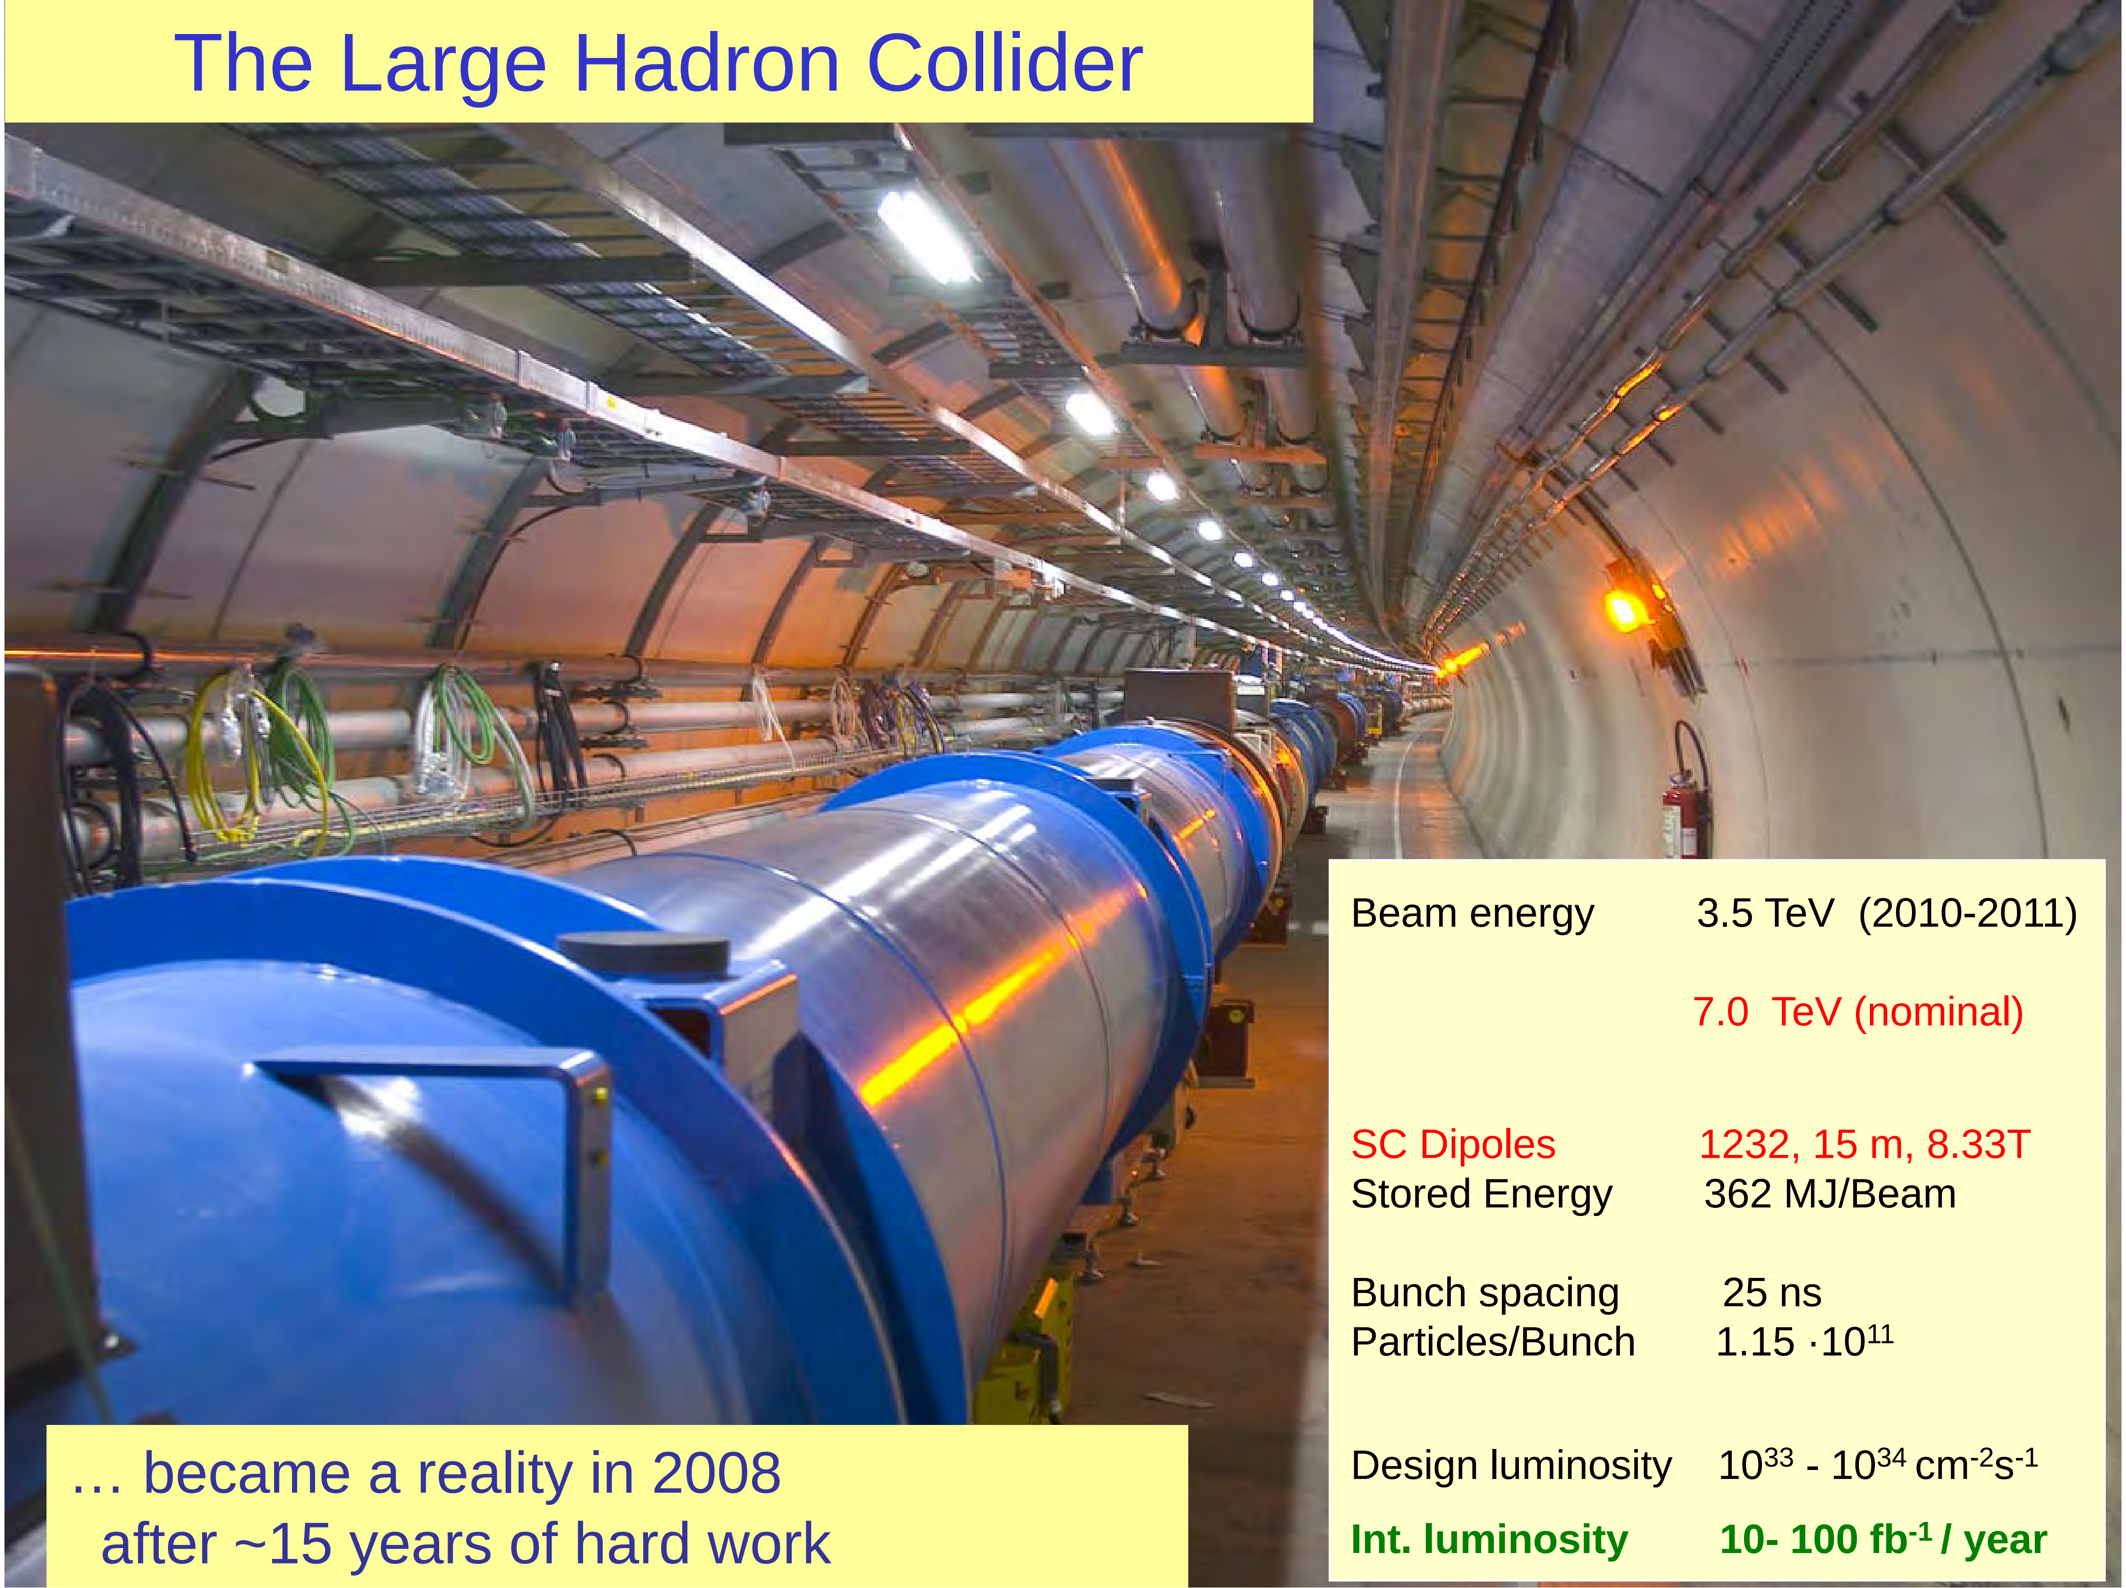
> 50 years of CERN history still alive and operational

The Large Hadron Collider



Beam energy	3.5 TeV (2010-2011)
	7.0 TeV (nominal)
SC Dipoles	1232, 15 m, 8.33T
Stored Energy	362 MJ/Beam
Bunch spacing	25 ns
Particles/Bunch	$1.15 \cdot 10^{11}$
Design luminosity	10^{33} - 10^{34} $cm^{-2}s^{-1}$
Int. luminosity	**10- 100 fb^{-1} / year**

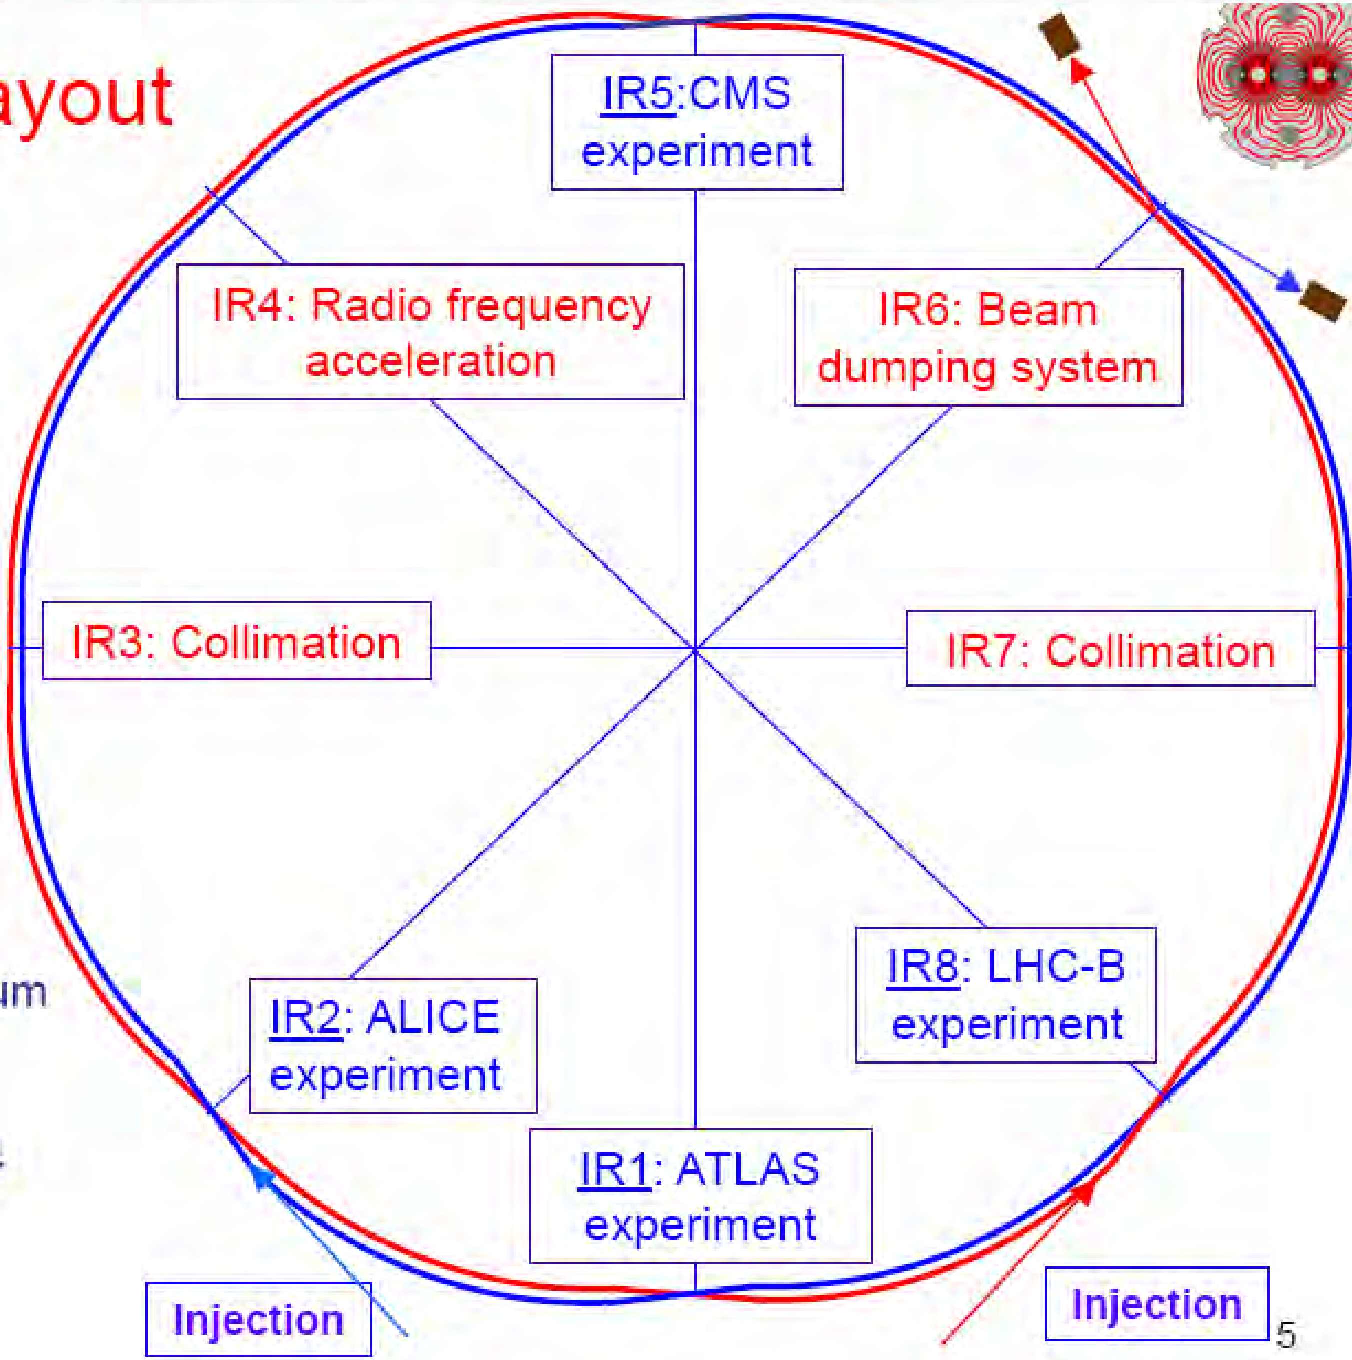
… became a reality in 2008
after ~15 years of hard work

LHC Layout

- 8 arcs (sectors)
- 8 long straight sections (700 m long):

  IR1 to IR8

- 2 separate vaccum chambers
- beams cross in 4 points

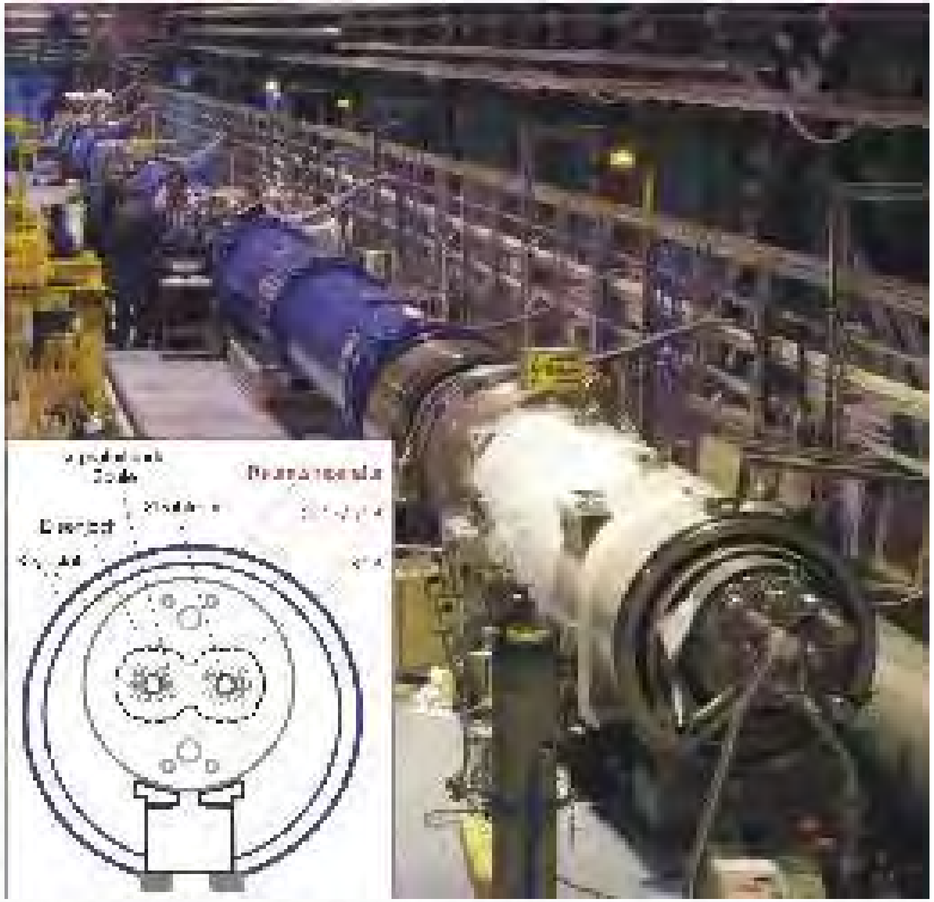


5

Important components of the accelerator

- Superconducting dipole magnets
  (the largest challenge)

  - Magnetic field of 8.33 Tesla
  - in total 1232, 15 m long
  - Operation temperature of 1.9 K
    (helium cooling)



Magnetic field for dipoles
p (TeV) = 0.3 B(T) R(km)

For p = 7 TeV and R = 4.3 km

→ B = 8.33 T
→ Current 12 kA

Important components of the accelerator

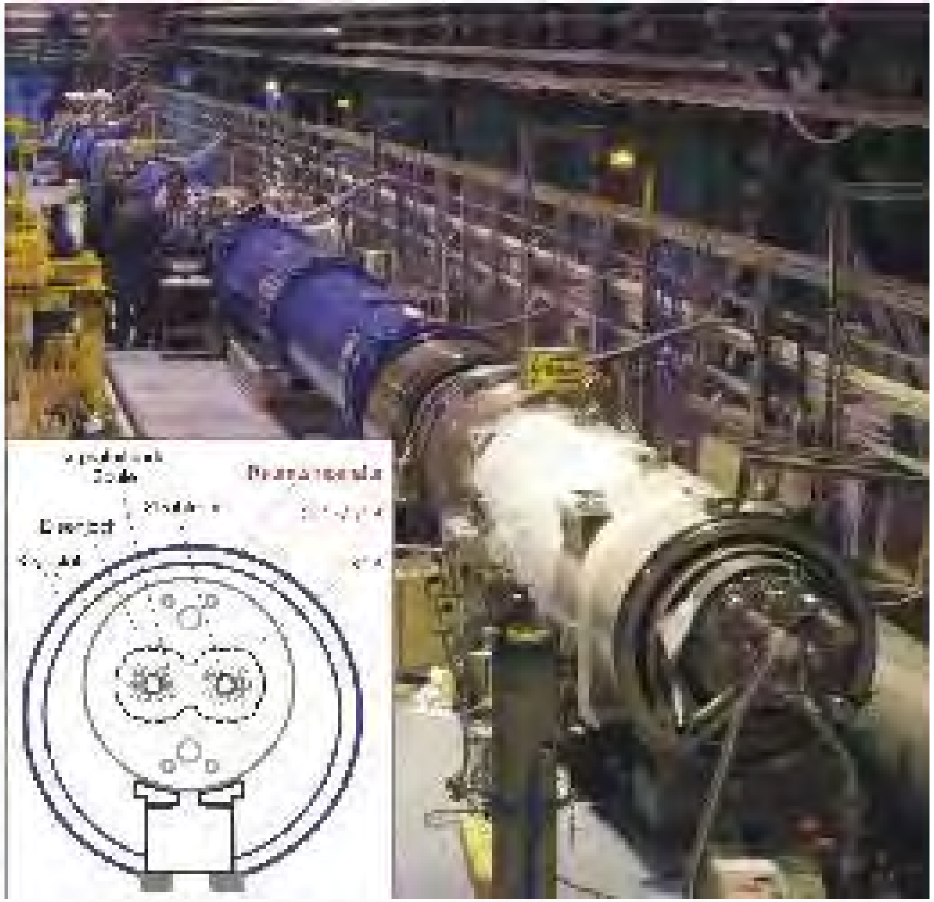
- Superconducting dipole magnets
  (the largest challenge)

  - Magnetic field of 8.33 Tesla
  - in total 1232, 15 m long
  - Operation temperature of 1.9 K
    (helium cooling)

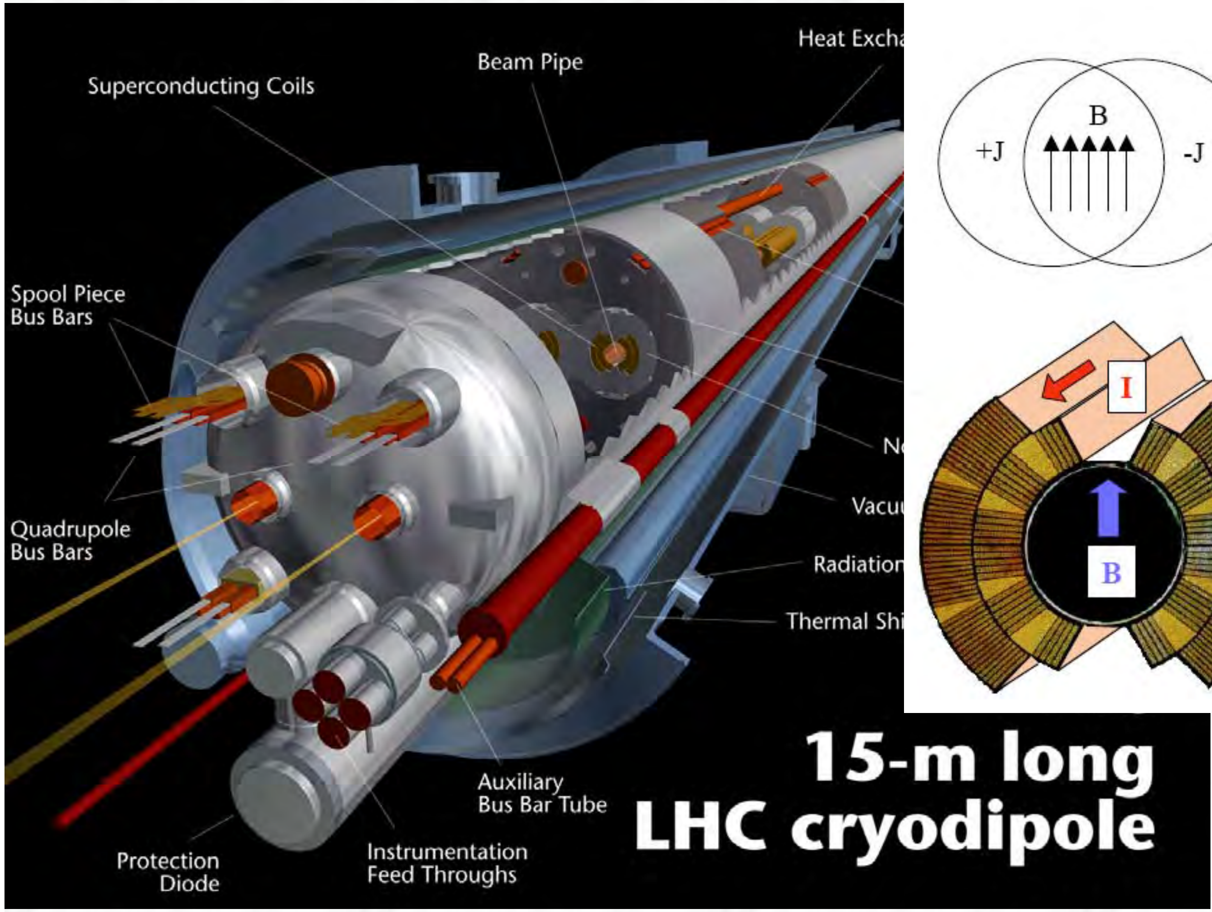
- Eight acceleration structures,
  Field gradient of 5 MV/m

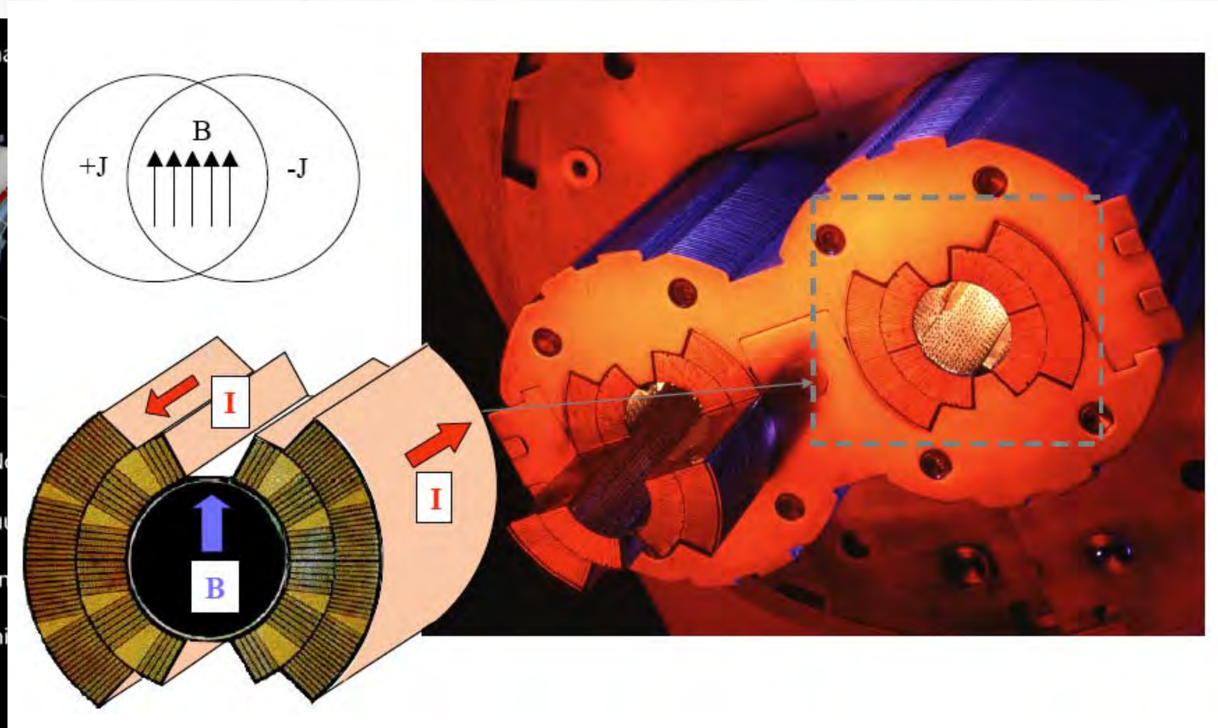
- Unprecedented complexity

  (in total: ~10.000 magnets powered by 1.700 electrical circuits, large stored energy, complex protection systems)



LHC Accelerator Challenge: Dipole Magnets





Coldest ring in the Universe ?   1.9 K

LHC magnets are cooled with pressurized superfluid helium

Two beams in one dipole magnet, 8.33 Tesla
(opposite magnetic dipole fields,
 protons circulating in opposite
 directions)
15 m long, mass of 30 tons

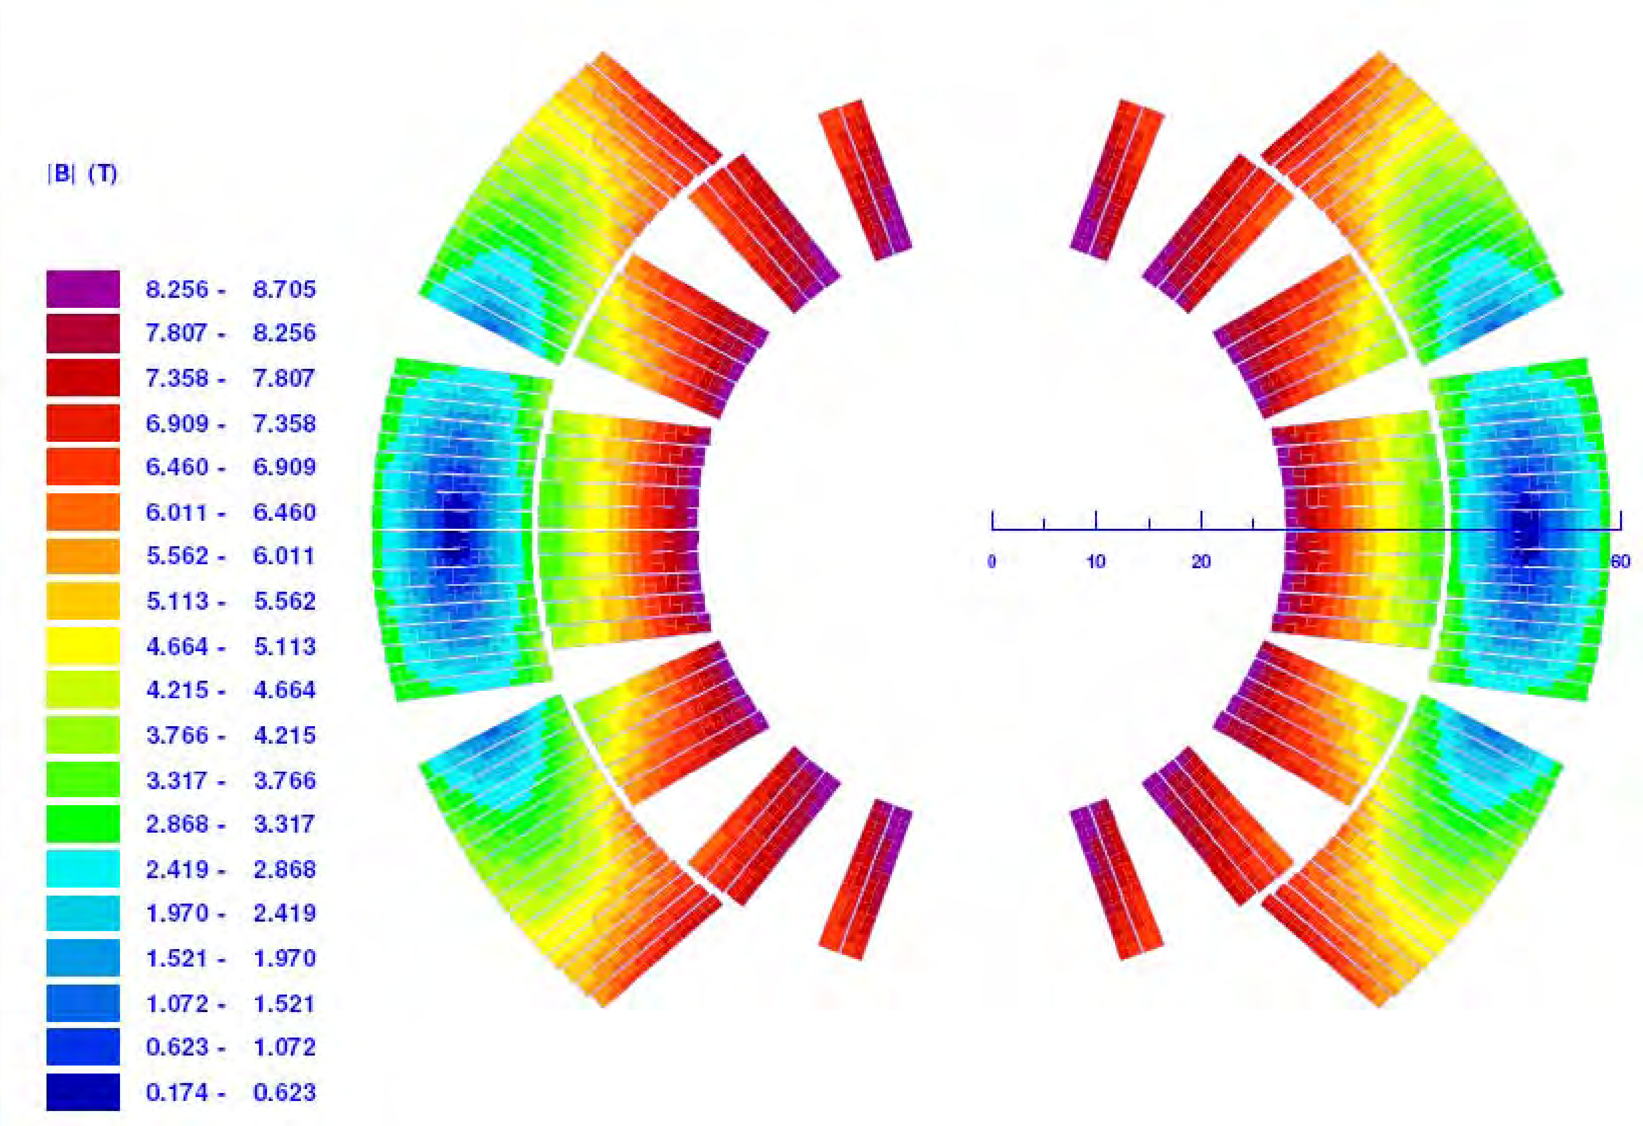
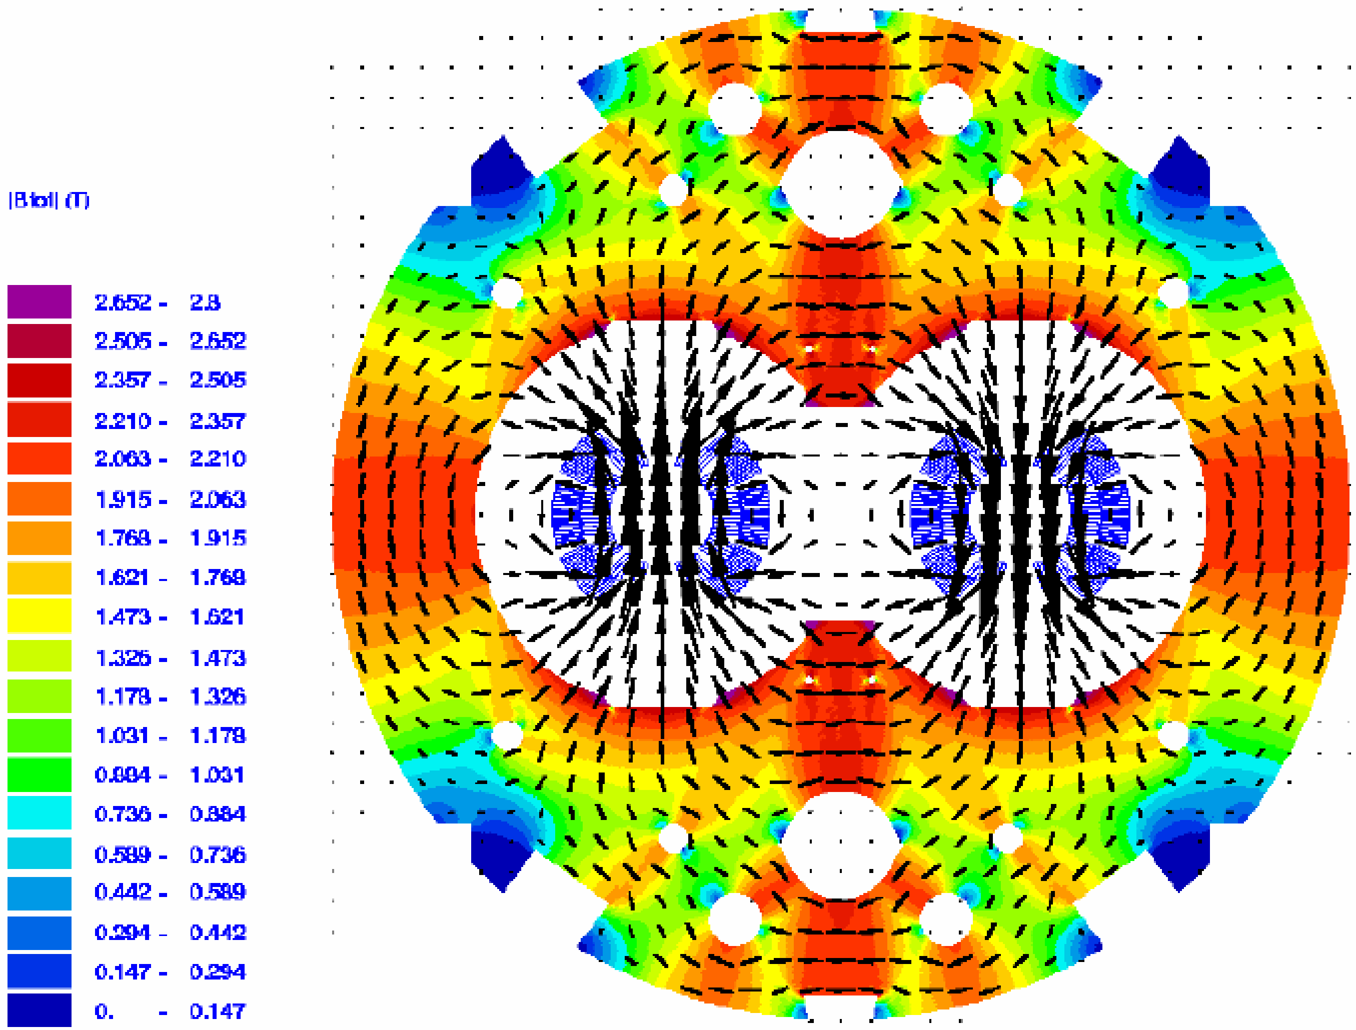
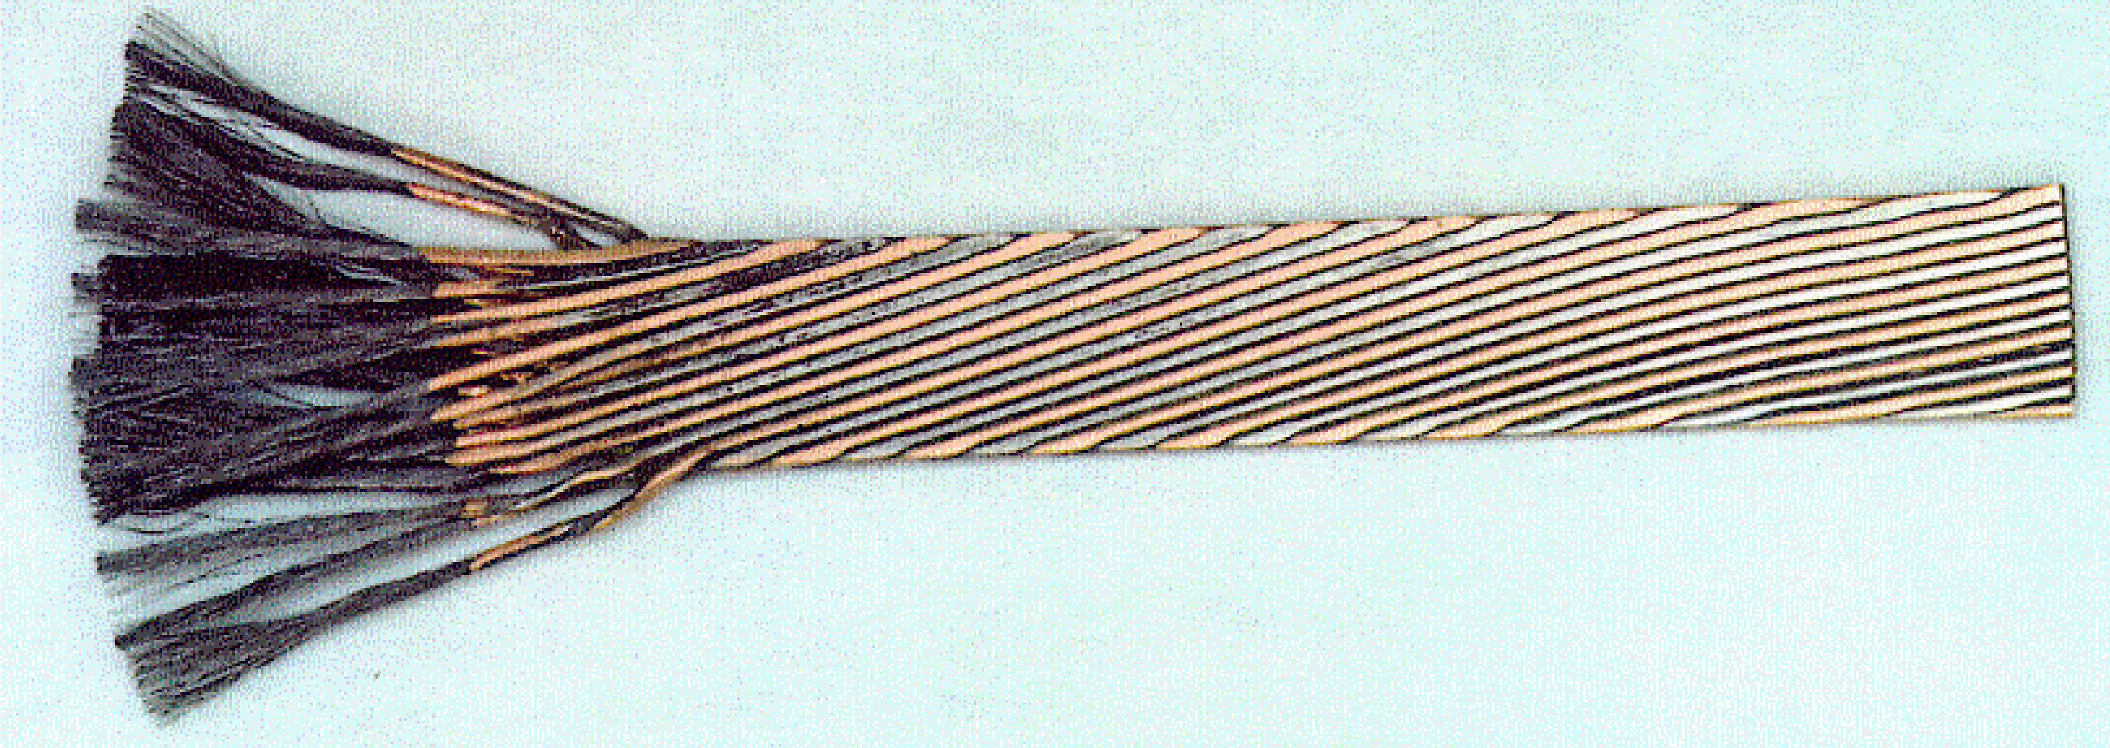
Distribution of conductors in the dipole coil



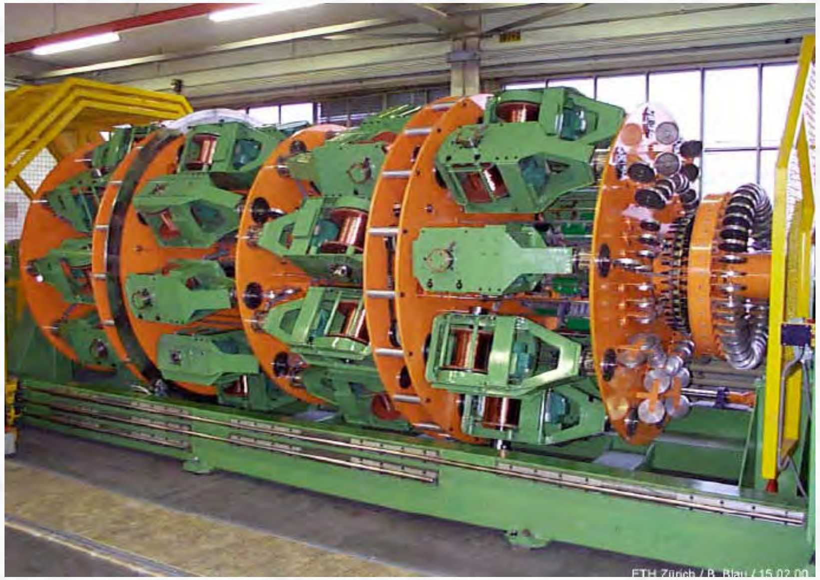
Dipole magnetic flux plot

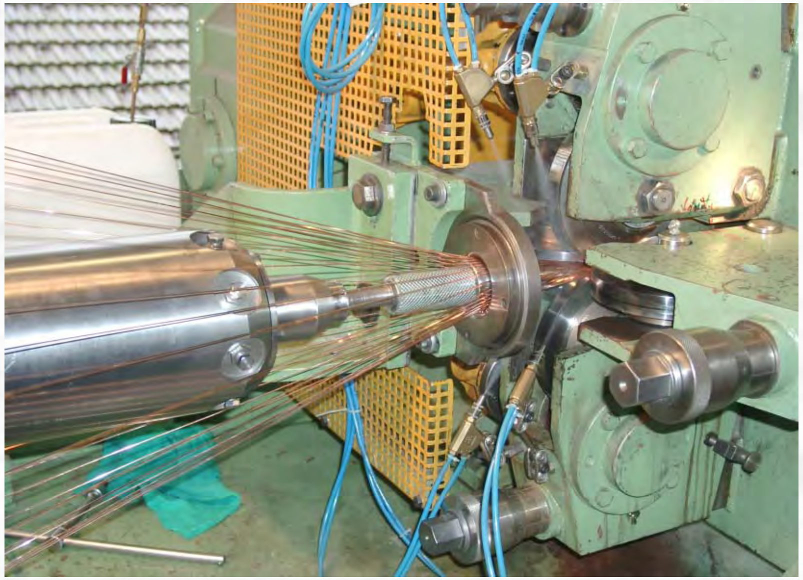


Sample of superconducting cable



Production of superconducting wires & cables





Manufacturing of superconducting coils

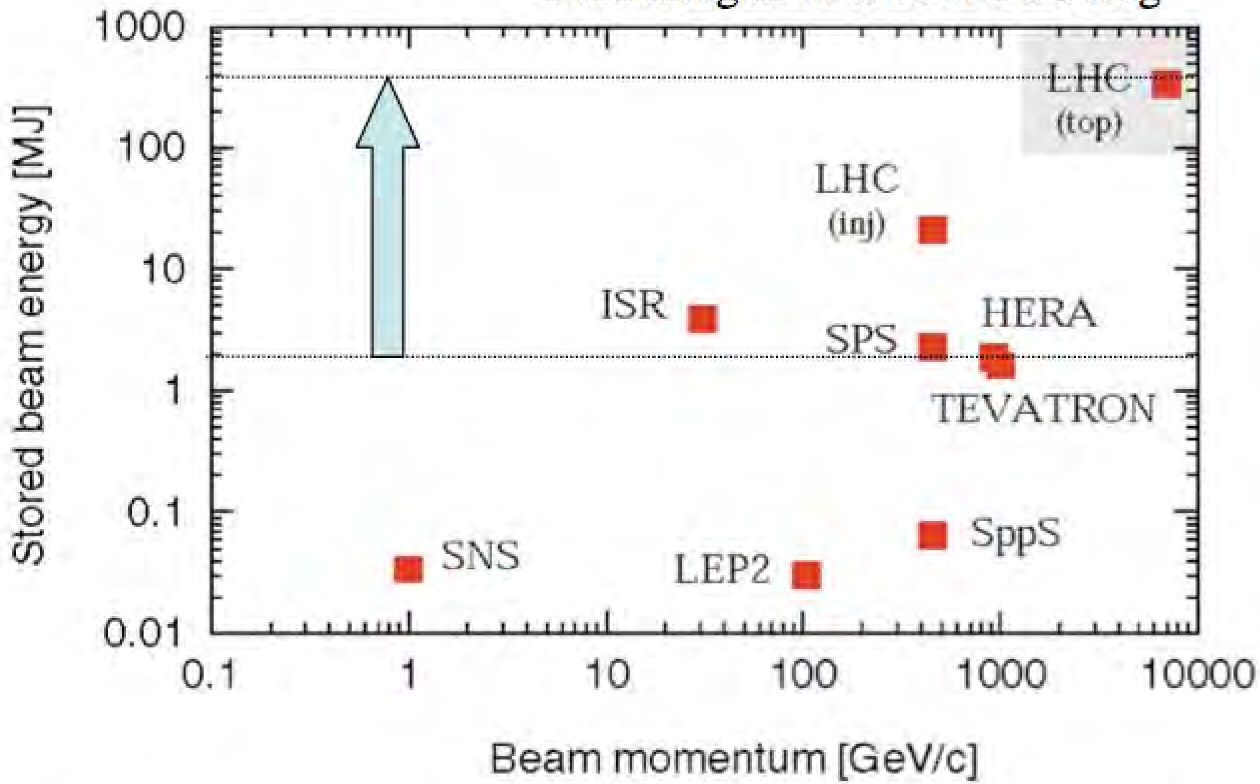
Assembly of dipole cold masses

Descent of the last dipole magnet, 26 April 2007

30’000 km underground transports at a speed of 2 km/h!

The total stored energy of the LHC beams

Nominal LHC design: 3×10^{14} protons accelerated to 7 TeV circulating at 11 kHz in a SC ring



LHC: > 100 x higher stored energy and small beam size: ~ 3 orders of magnitude in energy density and damage potential. Active protection (beam loss monitors, interlocks) and collimation for machine and experiments essential.
Only the specially designed beam dump can safely absorb this energy.

Beam parameters, LHC compared to LEP

	LHC	LEP2
Momentum at collision, TeV/c	7	0.1
Nominal design Luminosity, $cm^{-2}s^{-1}$	1.00E+34	1.00E+32
Dipole field at top energy, T	1	1
Number of bunches, each beam	2808	4
Particles / bunch	1.15E+11	4.20E+11
Typical beam size in ring, µm	200-300	1800/140 (H/V)
Beam size at IP, µm	16	200/3 (H/V)

- **Energy stored in the magnet system: 10 GJoule**
- **Energy stored in one (of 8) dipole circuit: 1.1 GJ**
- **Energy stored in one beam: 362 MJ**
- **Energy to heat and melt one kg of copper: 0.7 MJ**

Kin. energy of Airbus A380, 560t at 700 km/h.

the LEP2 total stored beam energy was about 0.03 MJ

LHC: From first ideas to realisation

26 y

1982 : First studies for the LHC project
1983 : Z discovered at SPS proton antiproton collider
1989 : Start of LEP operation ~ 92 GeV, Z-factory
1994 : Approval of the LHC by the CERN Council
1996 : Final decision to start the LHC construction
1996 : LEP2 operation towards ~ 200 GeV, W^+W^-
2000 : End of LEP operation
2002 : LEP equipment removed
2003 : Start of the LHC installation - infrastructure
2005 : Start of Magnet installation in LHC tunnel
2007 : Installation complete, starting cooldown
2008 : Commissioning with beam and first collisions

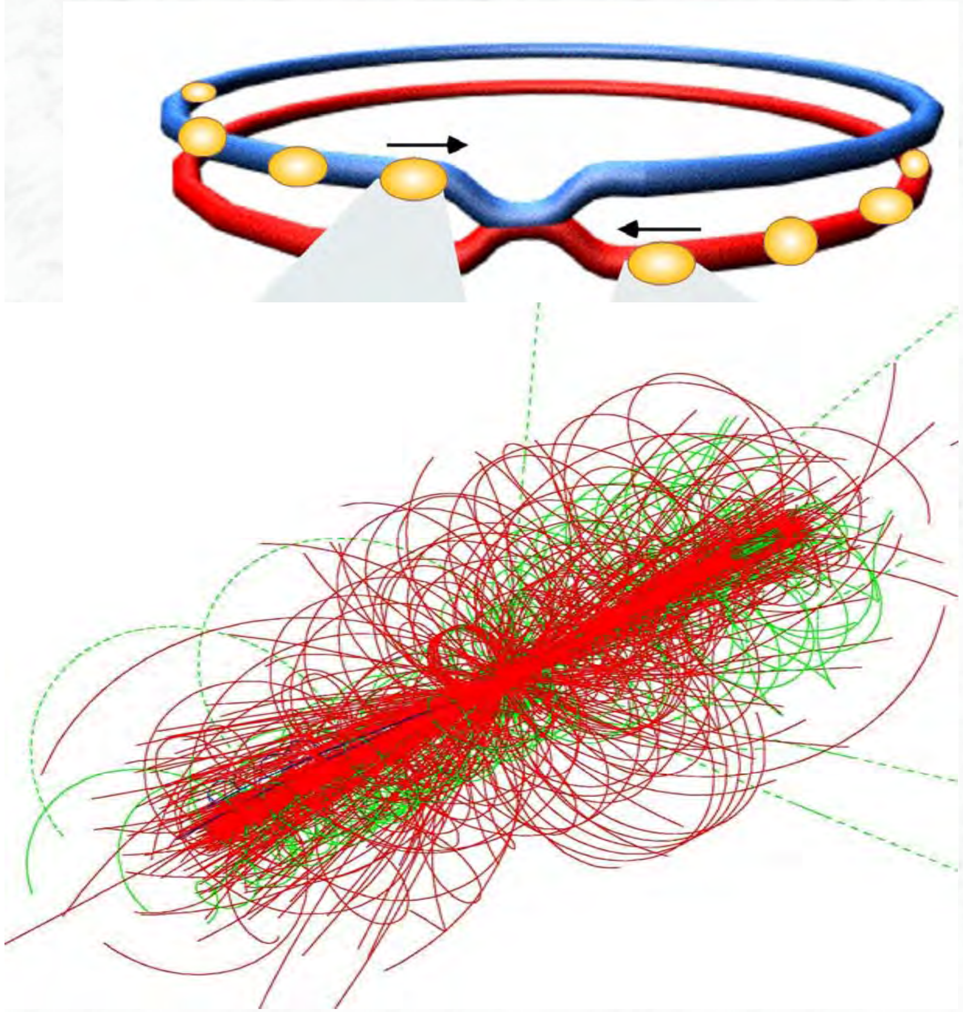
Proton-proton collisions at the LHC



Proton–proton:

2808 x 2808 bunches
Separation: 7.5 m (25 ns)

10^{11} protons / bunch
crossing rate of p bunches: 40 Mio / s
Luminosity: L = 10^{34} cm^{-2} s^{-1}

~10^{9} pp collisions / s
(superposition of > 20 pp interactions per crossing: **pile-up**)

~1600 charged particles in the detector

⇒ high particle densities,
high requirements on detectors

An excellent LHC start: first beams – Sept 10, 2008

Incident on 19th Sep. 2008, repair, comeback…..

- A resistive zone developed in an electrical bus bar connection
- Electrical arc → punctured the helium enclosure
- Helium release under high pressure
- Relief discs unable to maintain the pressure rise below 0.15 MPa → large pressure forces

- Lot of repair work during 2009

(14 quadrupole and 39 dipole magnets replaced, electrical interconnections repaired, larger helium pressure release ports installed,…..)

- A very successful re-start in Nov. 2009

LHC re-start in Nov. 2009

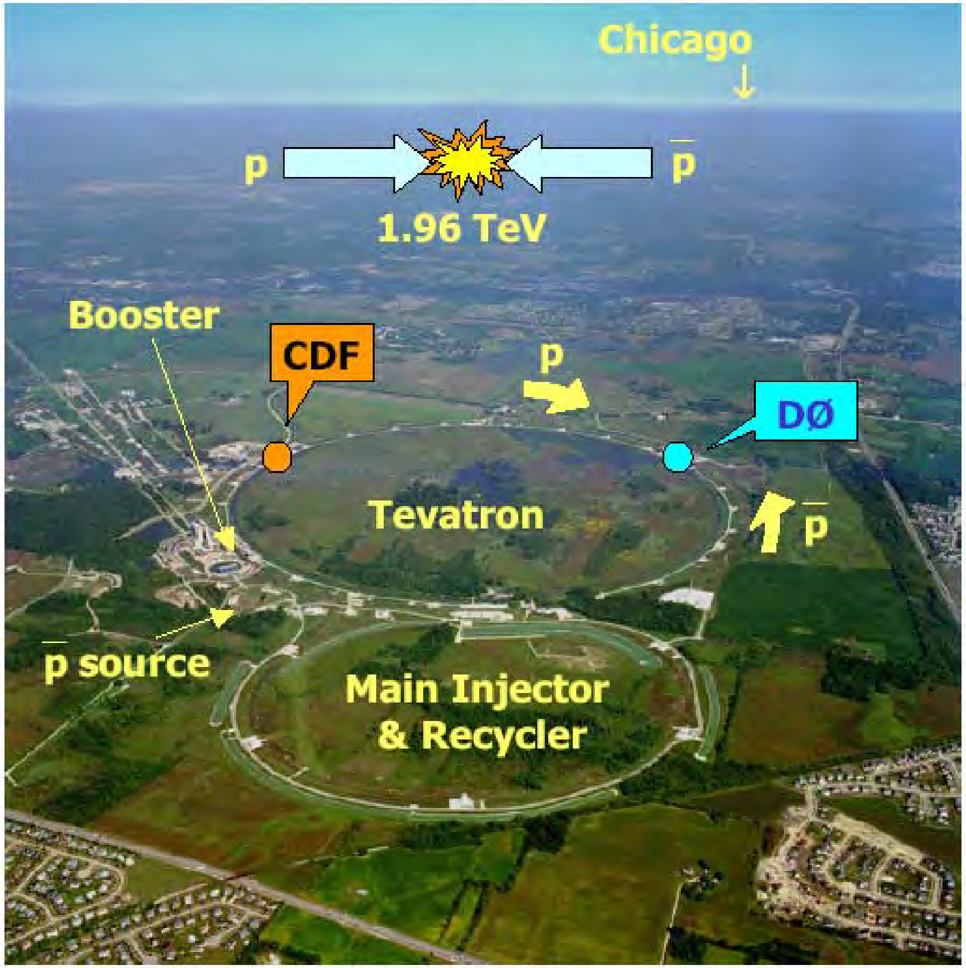
1.4 The Fermilab Tevatron collider

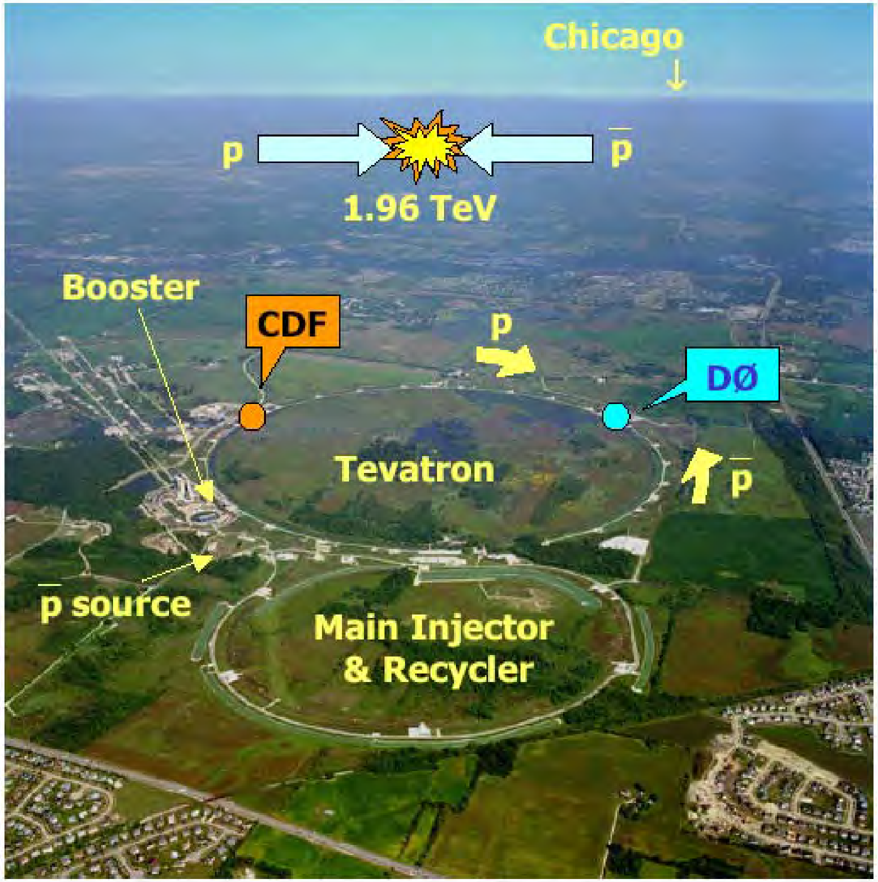


The Tevatron Collider at Fermilab

- **Proton antiproton collider**
  - 6.5 km circumference
  - Beam energy 0.98 TeV, $\sqrt{s}$ = 1.96 TeV
  - 36 bunches, 396 ns separation (time between crossings)

- **2 Experiments: CDF and DØ**

- **Main challenges:**
  - Antiproton production and storage
    → luminosity, stability of operation

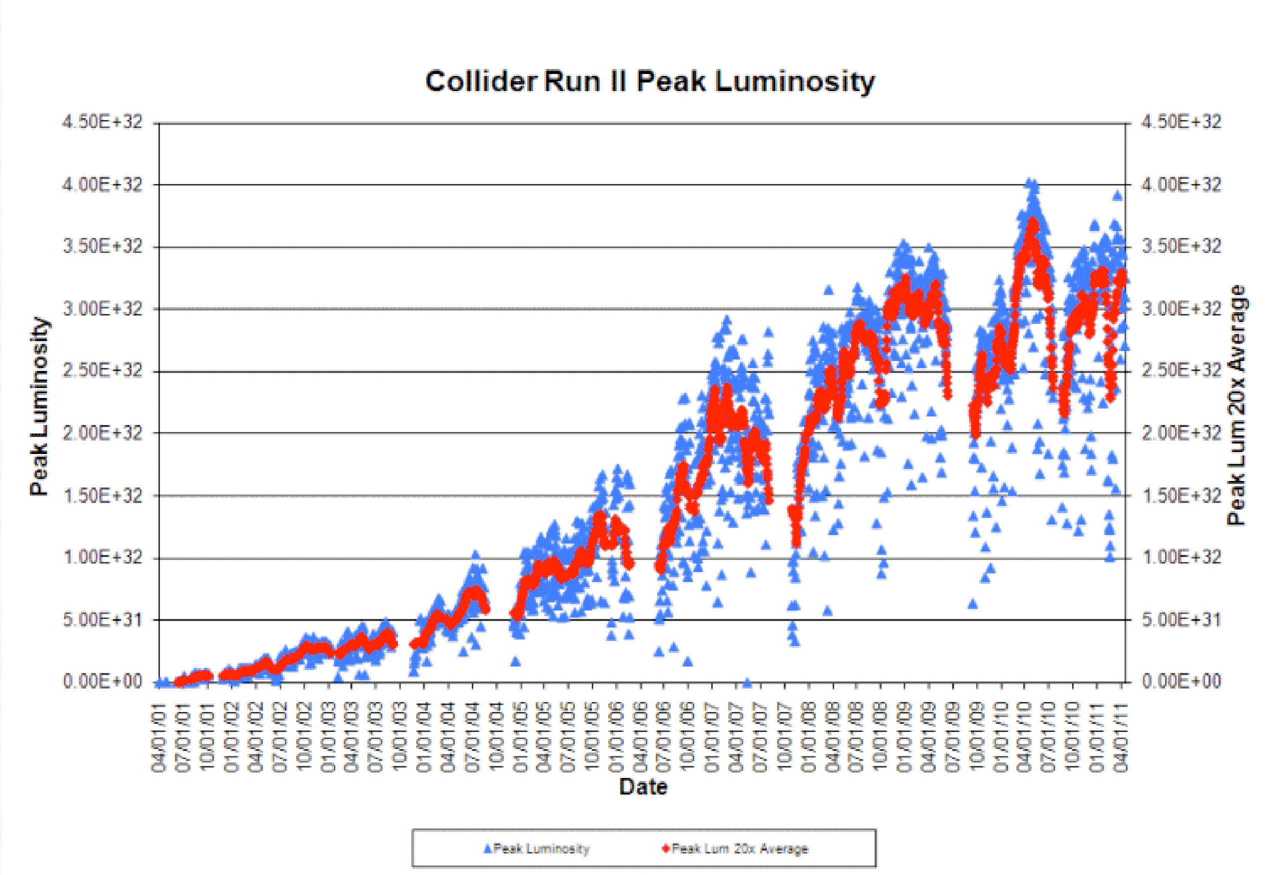


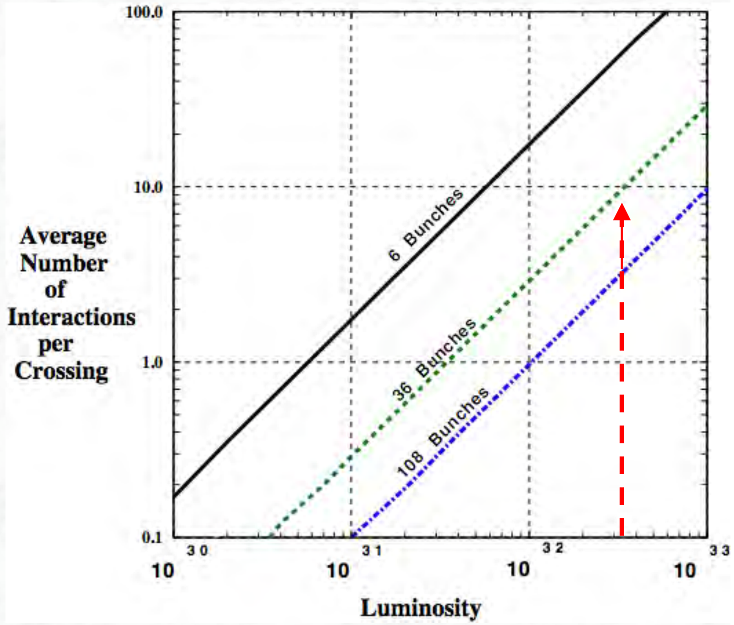
Collider is running in so called Run II (since 2001)
[Run I from 1990 – 1996, int. luminosity: 0.125 fb^{-1}, Top quark discovery]

- **March 2001 – Feb 2006: Run II a, $\int L\,dt$ = 1.2 fb^{-1}**
- **July 2006 - 2011: Run II b, $\int L\,dt$ = 10 -12 fb^{-1}**

Tevatron performance

Peak luminosities of the machine as a function of time

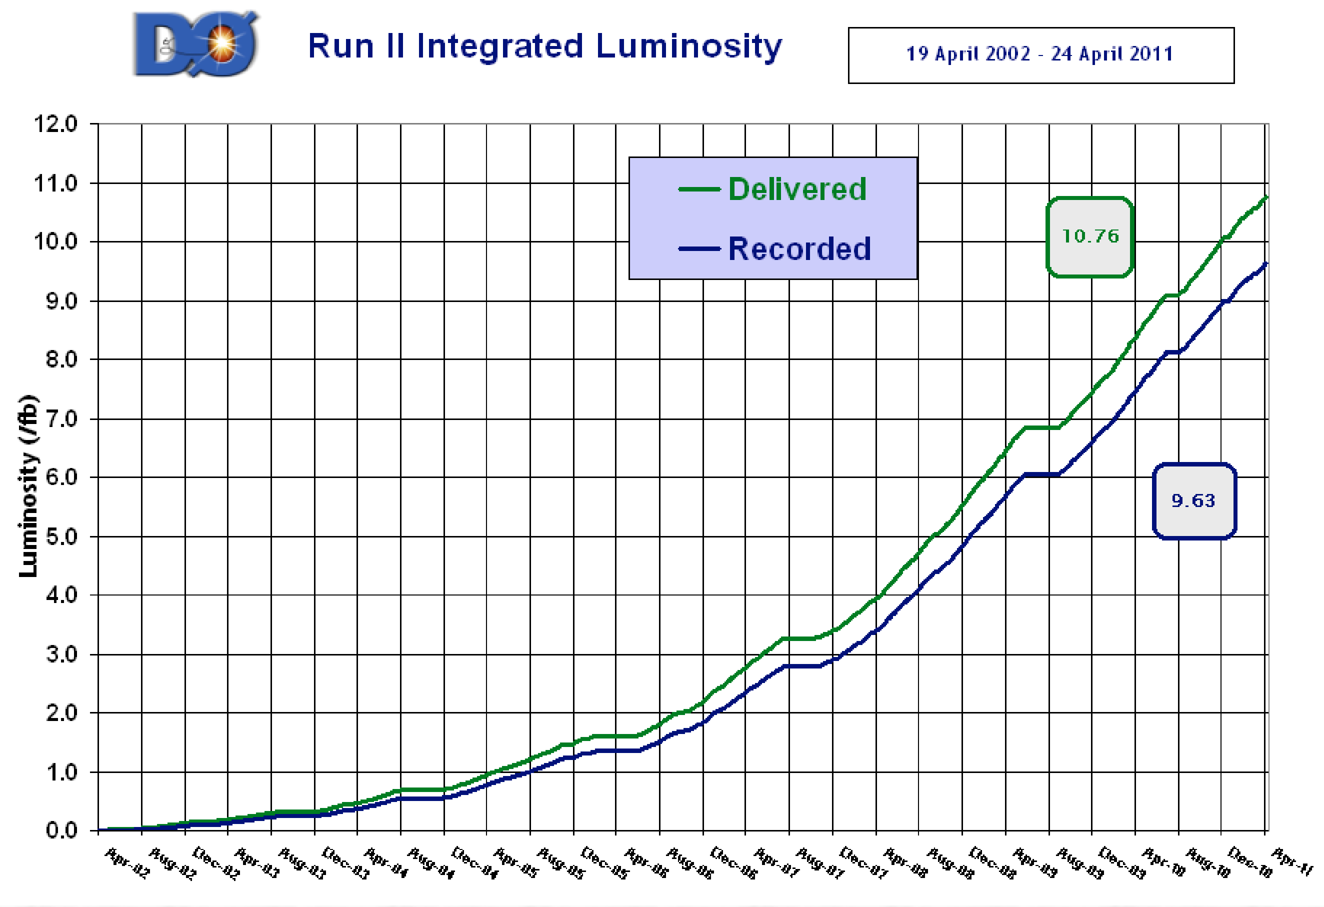




- Peak luminosity of $4 \cdot 10^{32}$ cm^{-2} s^{-1}
- Corresponds to ~10 interactions per bunch crossing
  (superposition of minimum bias events on hard collision)

The integrated Tevatron luminosity (until April 2011)

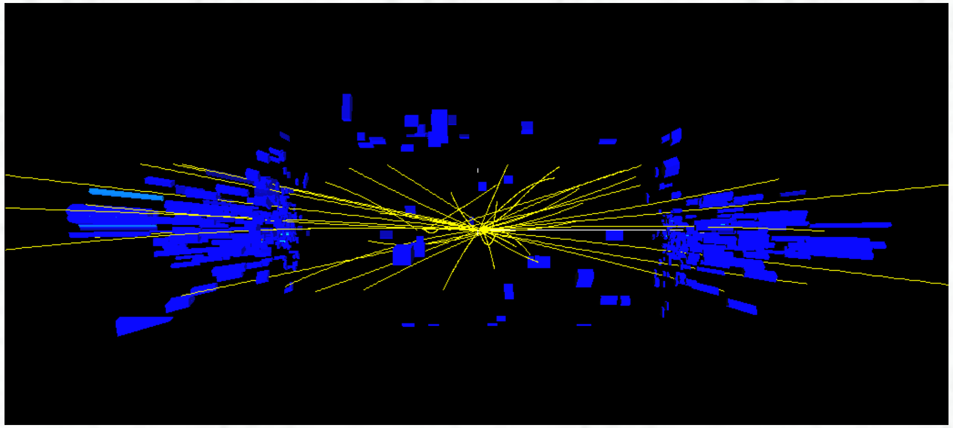
- After a slow start-up (2001 – 2003), the Tevatron accelerator has reached an excellent performance
- Today, Tevatron delivers a data set equal to Run I (~100 pb^{-1}) every 2 weeks
- Integrated luminosity delivered to the experiments so far ~ 10.8 fb^{-1}
- Anticipate an int. luminosity of ~12 fb^{-1} until end of 2011.



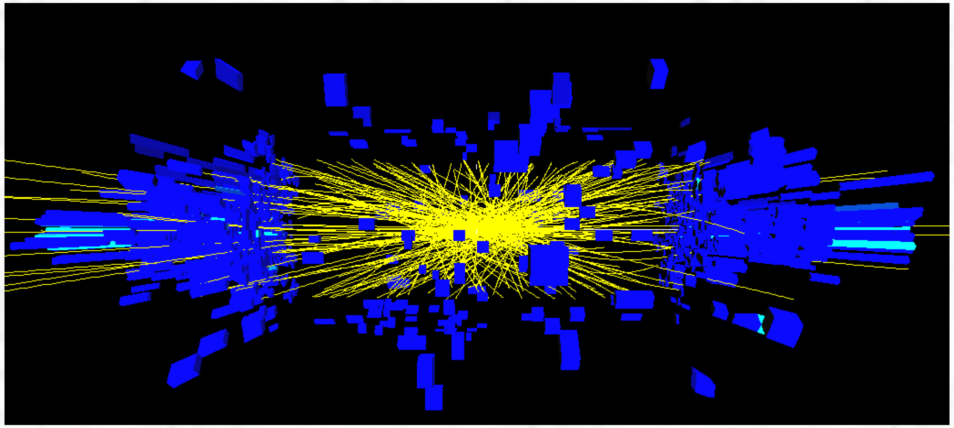
Data corresponding to an int. luminosity of up to ~8 fb^{-1} analyzed…

Challenges with high luminosity

Min. bias pileup at the Tevatron, at $0.6 \cdot 10^{32}$ cm^2s^{-1}



... and at $2.4 \cdot 10^{32}$ cm^2s^{-1}

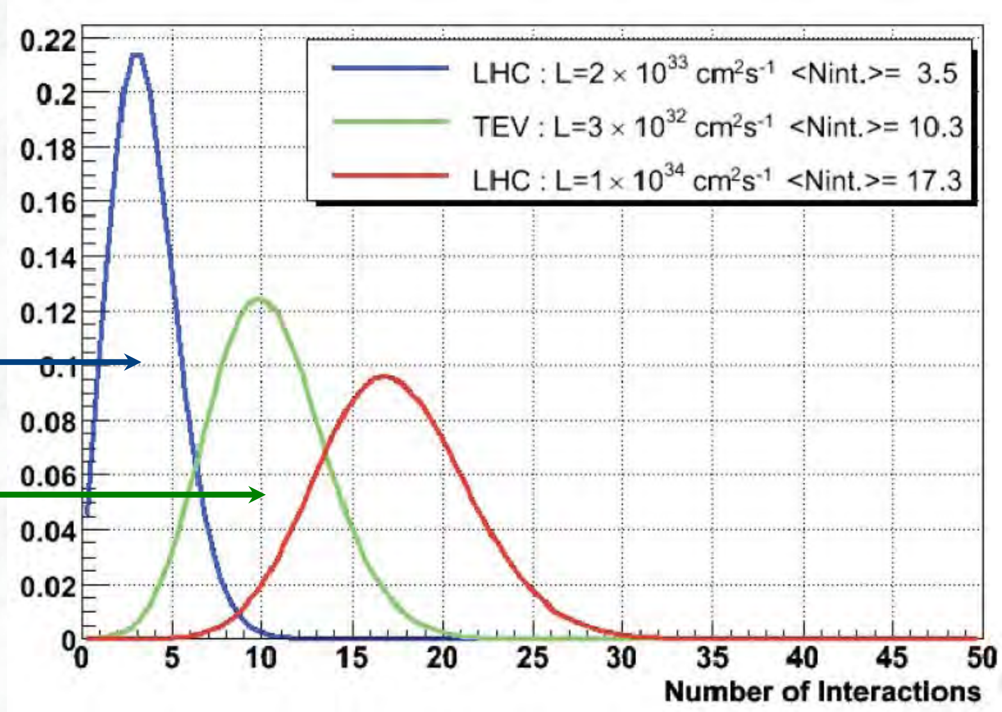


Average number of interactions:

LHC: initial “low” luminosity run

(L=2 $\cdot 10^{33}$ cm^2s^{-1}): <N>=3.5

TeV: (L=3 $\cdot 10^{32}$ cm^2s^{-1}): <N>=10



Comparison of the LHC and Tevatron machine parameters

	LHC (design)	Tevatron (achieved)
Centre-of-mass energy	**14 TeV**	**1.96 TeV**
Number of bunches	**2808**	**36**
Bunch spacing	**25 ns**	**396 ns**
Energy stored in beam	**360 MJ**	**1 MJ**
Peak Luminosity	**10^{33}-10^{34} $cm^{-2}s^{-1}$**	**3.5 x 10^{32} $cm^{-2}s^{-1}$**
Integrated Luminosity / year	**10-100 fb^{-1}**	**~ 2 fb^{-1}**

- 7 times more energy (after initial 3.5 TeV phase)
- Factor 3-30 times more luminosity
- Physics cross sections factor 10-100 larger
