4. Phenomenology of proton-proton collisions

- 4.1 Introduction
- 4.2 Hard scattering formalism
- 4.3 Parton distribution functions
- 4.4 Soft proton-proton interactions

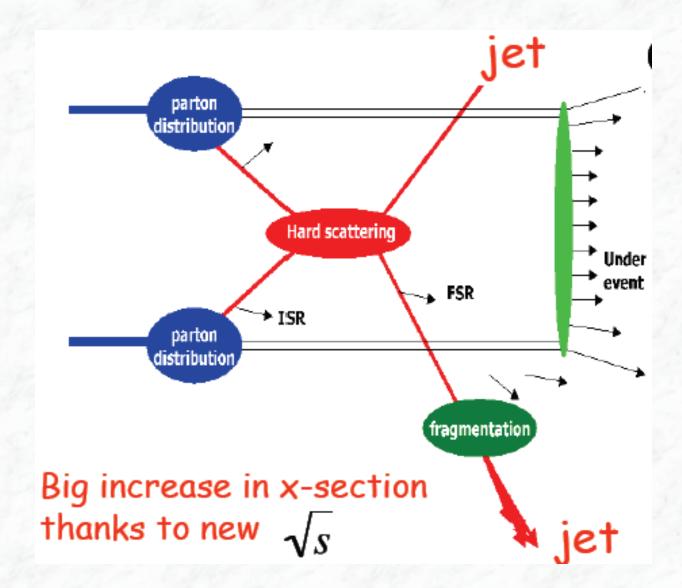

4.1 Introduction

Total and elastic cross section for pp collisions as a function of the laboratory beam momentum and and the total centre-of-mass energy (Particle data group).

Total and elastic cross section for proton-antiproton collisions as a function of the laboratory beam momentum and and the total centre-of-mass energy (Particle data group).

 $\sigma(pp \to A + X) = \sum_{i,j} \int f_{q_i}(x_i, Q^2) f_{q_j}(x_j, Q^2) \sigma(q_i q_j \to A) dx_i dx_j$

4.2 Hard scattering formalism

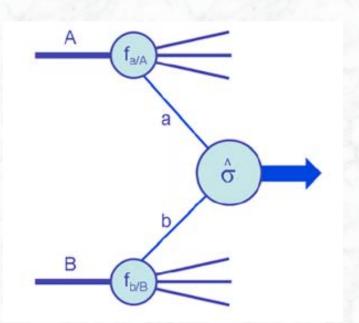

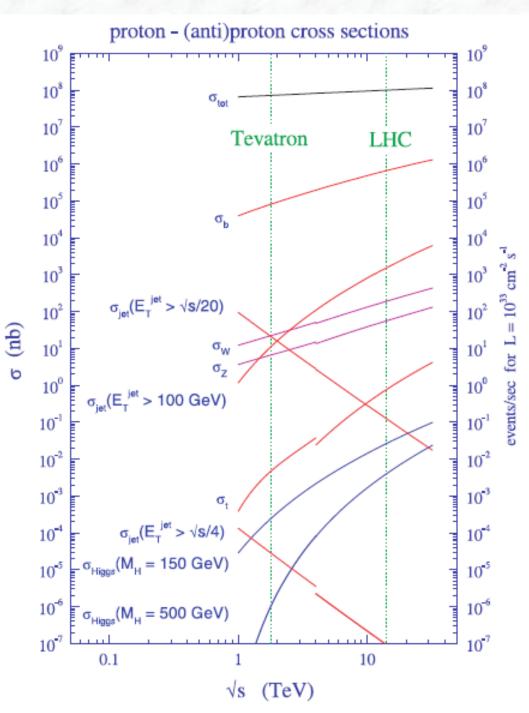

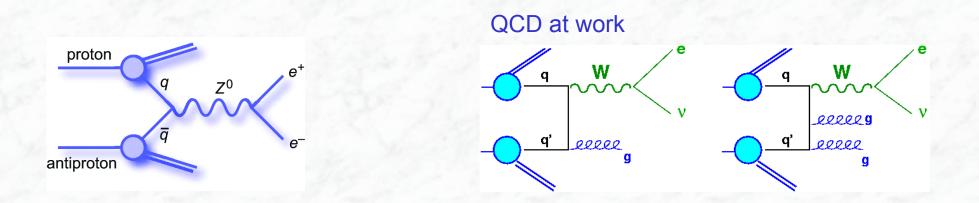

Illustration of a hard proton-proton interaction

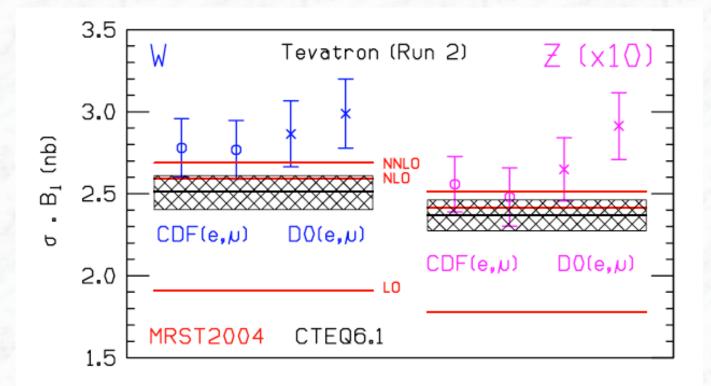

Cross sections for important hard scattering Standard Model processes at the Tevatron and the LHC colliders

QCD aspects in W/Z (+ jet) production

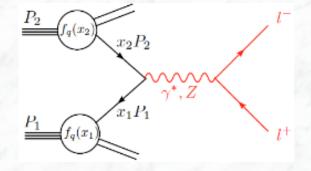

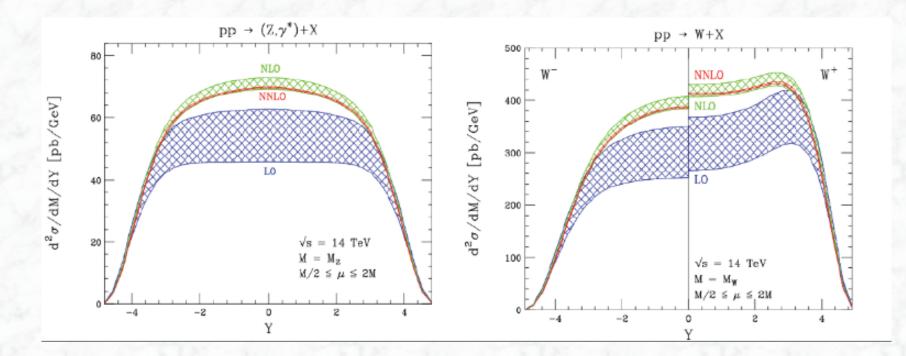

- Important test of NNLO Drell-Yan QCD prediction for the total cross section
- Test of perturbative QCD in high p_T region (jet multiplicities, p_T spectra,....)
- Tuning and "calibration" of Monte Carlos for background predictions in searches at the LHC

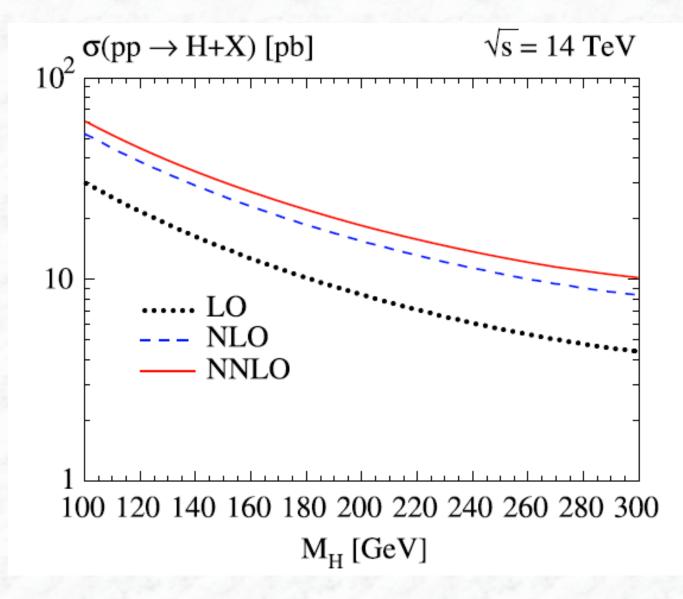

Predictions for the W and Z total cross section at the Tevatron, using MRST2004 and CTEQ6.1 pdfs, compared with measurements from the CDF and D0 experiments. The MRST predictions are shown at LO, NLO and NNLO. The CTEQ6.1 NLO predictions are shown together with the accompanying error band resulting from pdf uncertainties.

Example: Drell-Yan production of W/Z bosons

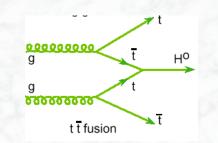

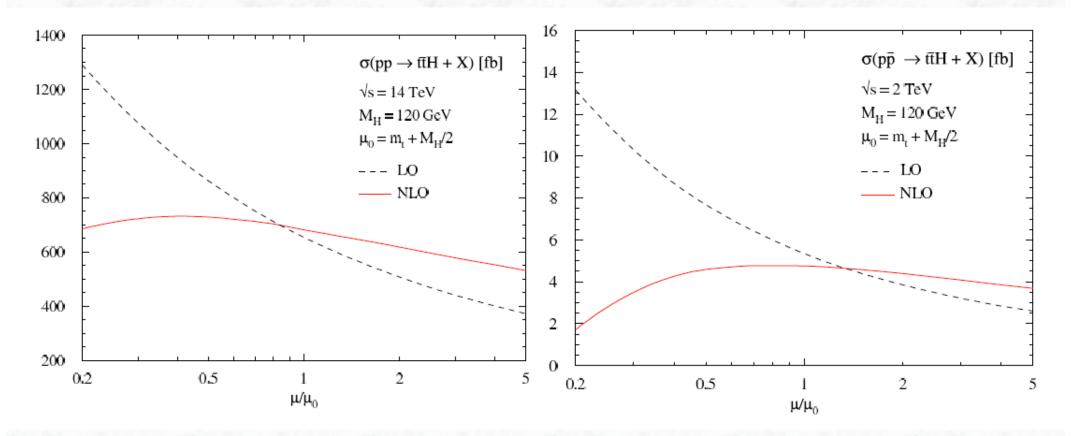

Rapidity distributions for Z and W^{\pm} production at LO, NLO, and NNLO

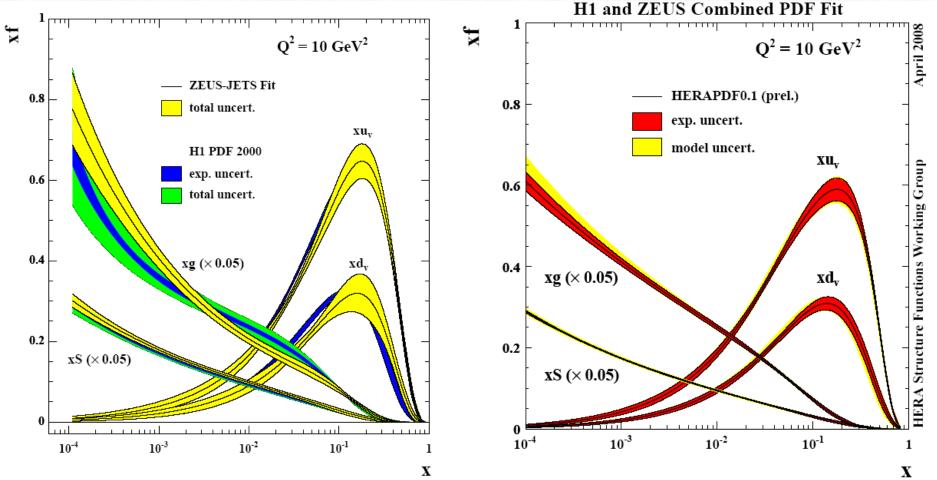

The inclusive Higgs boson production cross section as a function of the Higgs boson mass at LO, NLO and NNLO.

Variation of the ttH production cross section at the LHC 14 TeV pp collider (left) and at the Tevatron 2 TeV ppbar collider (right) with the renormalization and factorization scale $\mu = \mu_R = \mu_F$, varied around the value $\mu_0 = m_t + m_H / 2$.

4.3 Parton Distribution functions (pdf)

А

 The measurements of the parton distribution functions is the domain of Deep Inelastic Scattering (DIS) experiments

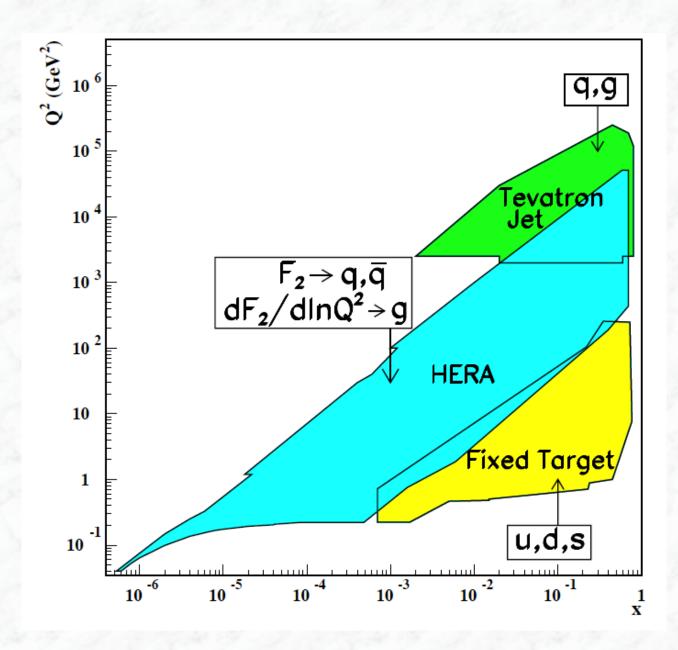

(BCDMS, NMC,..., HERA)

• In addition, many processes measured at hadron colliders contribute

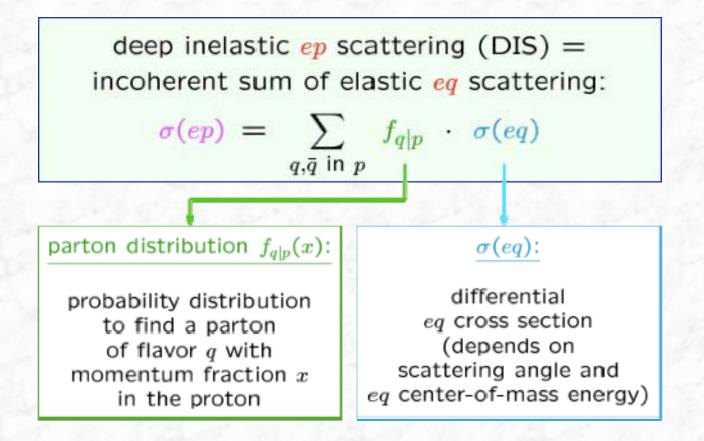

Other experimental data:		
reaction	subprocess	information
$p\bar{p} \to W + X$	$q \bar{q} ightarrow W$	u, d, u/d
$\nu^{\circ} N \rightarrow \mu^{+} \mu^{-} + X$	$ u s ightarrow \mu c$	8
$pp, pN \to \ell^+ \ell^- + X$	$q ar q o \ell^+ \ell^-$	\bar{d}/\bar{u}
$hh \to \gamma + X$	$qg ightarrow q\gamma$	g
	gg ightarrow gg	
$p\bar{p} \rightarrow \text{jets} + X$	$gq \rightarrow gq$	g,(q)
	$qq \rightarrow qq$	

History of Deep Inelastic Scattering (DIS) experiments

Kinematic domains in x and Q² probed by fixed-target and collider experiments, shown together with the constraints they make on the various parton distributions (from Particle Data Group).

So, if parton distributions are known, the cross sections can be predicted, or vice versa: from a measurement of the cross sections, the parton distributions can be inferred

Important: Q² dependence, QCD effects

 \Rightarrow isolated

٠

٠

- \Rightarrow energy \gtrsim 10 GeV
- One or more "central" jets
- Proton remnant energy deposition around beam pipe in p direction

 ϵ

q

p remnant

 γ, Z

e

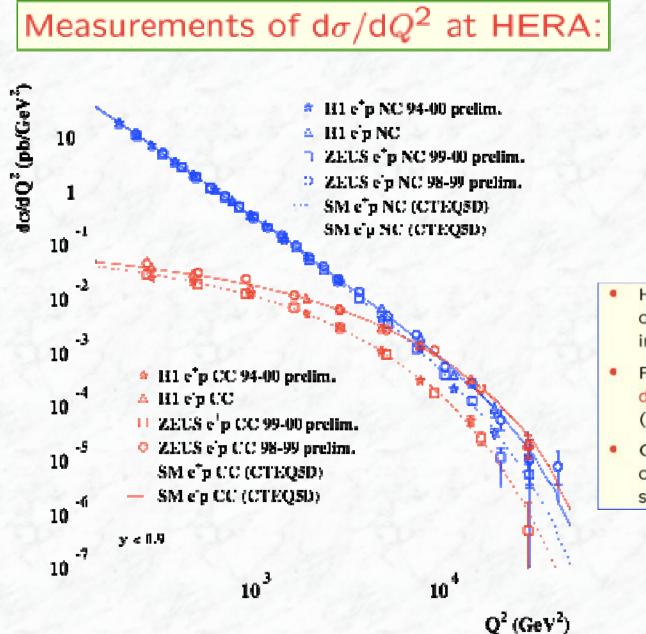

q

p

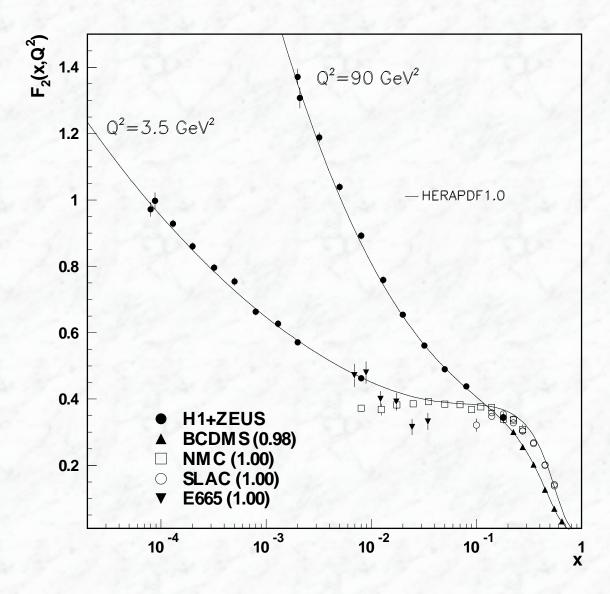

Charged Current (CC)

- Scattered neutrino
 - \Rightarrow invisible
 - ⇒ causes missing transverse momentum
- Hadronic final state
 ⇒ as in NC reactions

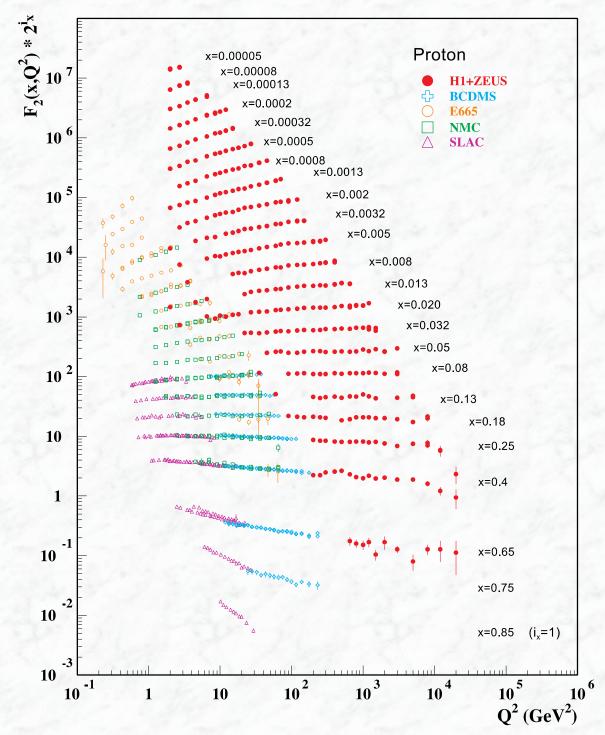

NC and CC cross sections

- HERA: first simulteneous measurements of NC and CC reactions, e⁺p und e⁻p in the same experiment.
- For $Q^2 \gtrsim M_{W,Z}^2$ we have $d\sigma/dQ^2(NC) \sim d\sigma dQ^2(CC)$ (electroweak unification).
- Cross sections vary by many orders of magnitude, measurements still statistics-dominated at high Q².

The legacy of HERA

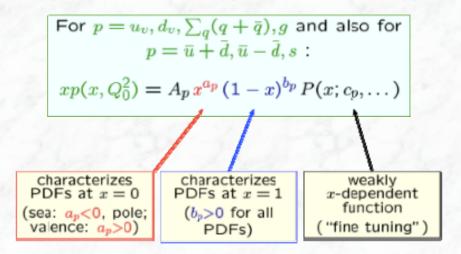

An enormous extension of the kinematic range both to high Q² and to low x

- low x: significant constraints on the gluon
- high Q²: W/Z exchange and probe of the electroweak sector.

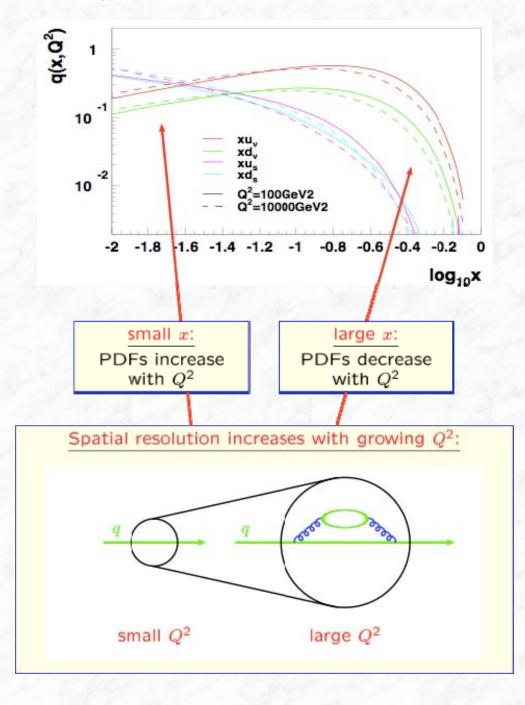

The principle of the pdf determination

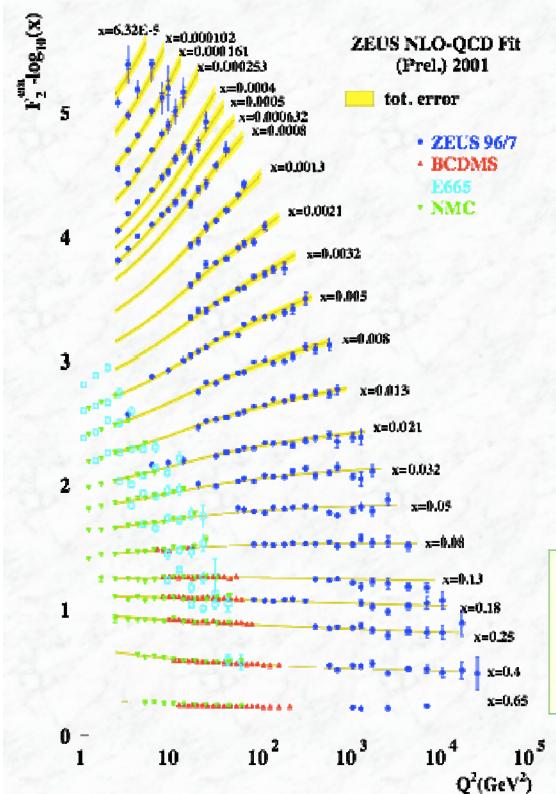

• The parton distribution functions cannot be described from first principles. A parametrization is performed at a reference scale Q_0 as a function of x

- The QCD evolution (DGLAP) is used to calculate the pdfs at a higher Q² scale (up to NLO, partly NNLO precision)
- Predictions for experimental observables (cross sections, structure functions, ...) are calculated
- pdf parameters are determined from a X² fit to the experimental data
- Fits are performed by several groups: CTEQ, MRST,

scaling violations via QCD effects

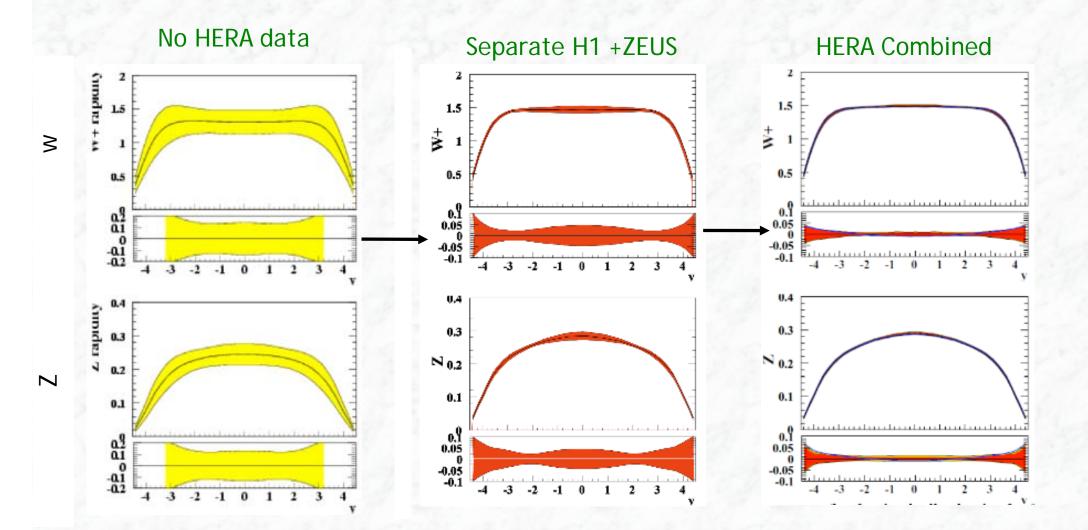

QCD fits to data

NC and CC DIS data

 Fixed target experiments: measurements of structure functions (different target nuclei)
 NC: BCDMS, NMC, E665, SLAC,...
 CC: CCFR, CDHS(W), CHARM, BEBC, ...

 Structure functions and cross sections from ZEUS and H1

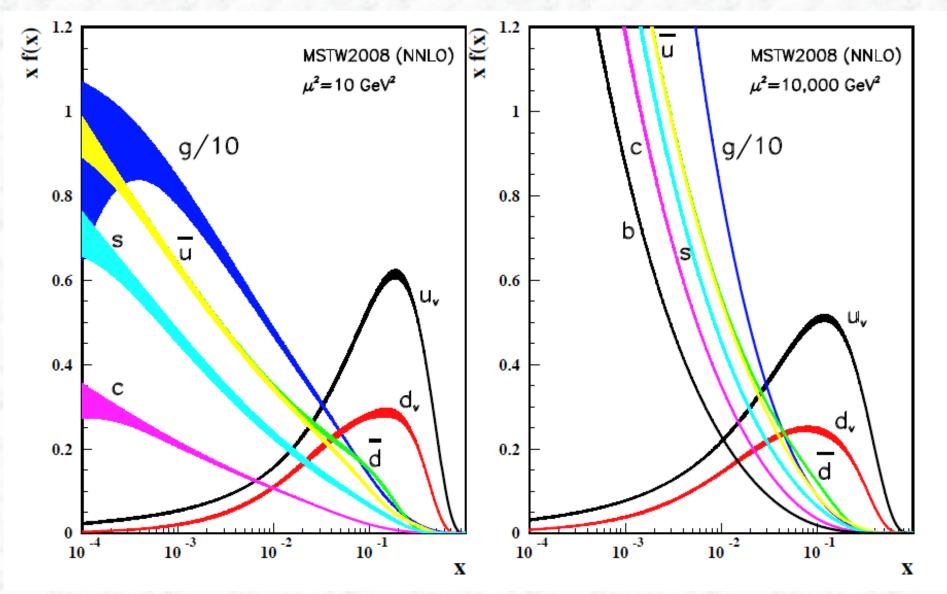

Impact of HERA data on the LHC: W/Z production as an example

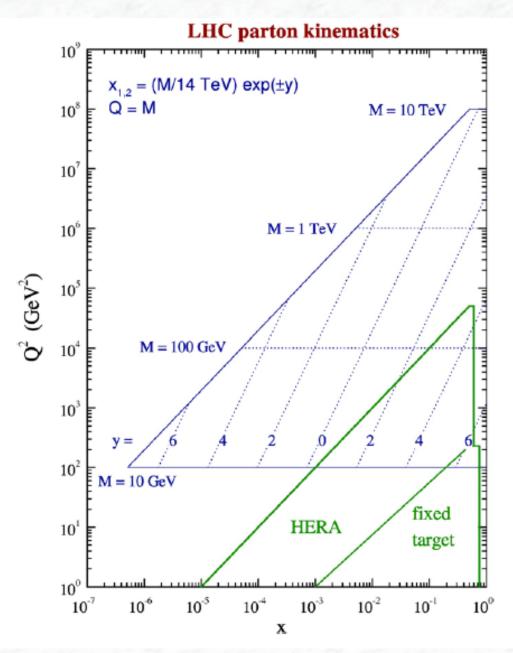

W and Z production cross sections and rapidity distributions are much more precisely known

(mainly due to better constrained low-x region (gluons), due to $gq \rightarrow Wq$ and $g \rightarrow qqbar$ splitting contributions producing the necessary antiquarks (sea))

Parton distribution functions (2010)

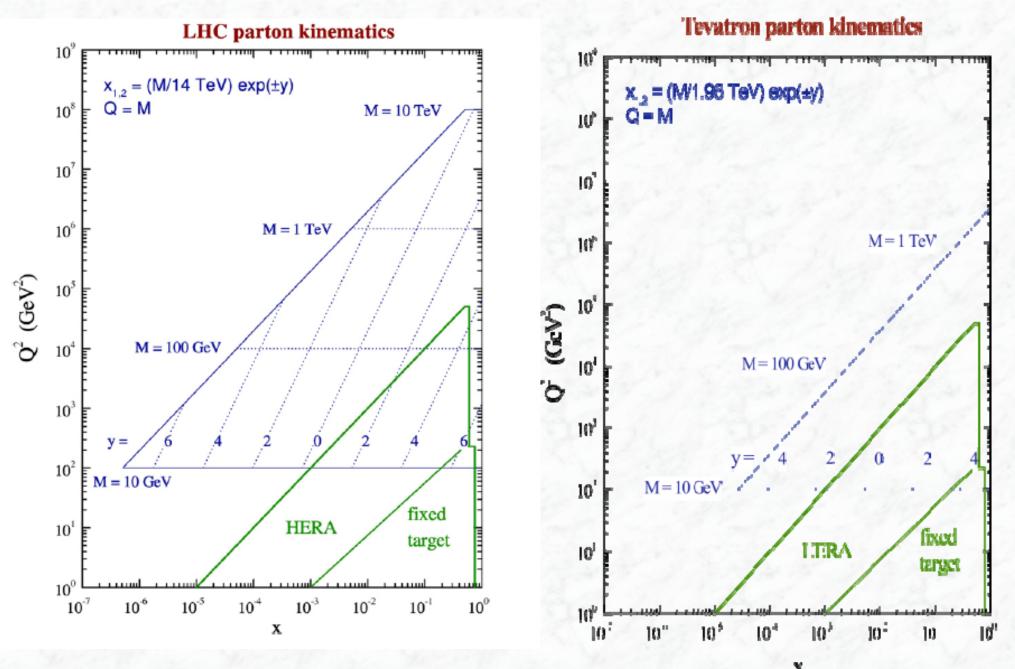

Distributions of x times the unpolarized parton distributions f(x), where f = u_v, d_v, ubar, dbar, s, b, g and their associated uncertainties using the NNLO MRST2006 parametrization at a scale μ^2 = 20 GeV² and μ^2 = 10.000 GeV².

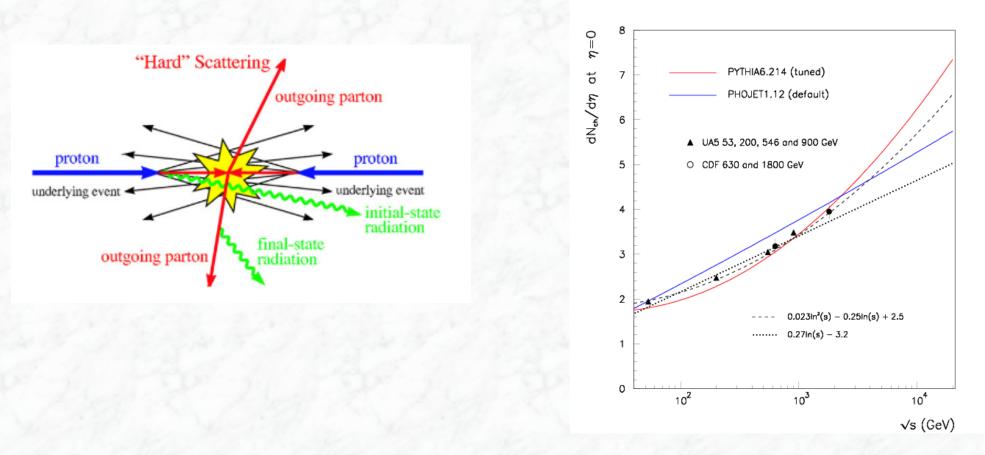

Graphical representation of the relationship between parton (x, Q²) variables and the kinematic variables corresponding to a final state of mass M with rapidity y at the LHC with $\sqrt{s} = 14$ TeV

Comparison between the Tevatron and the LHC (14 TeV)

For the same masses (e.g. 100 GeV): x-values about 10 times lower at the LHC

4.4 Soft proton-proton interactions

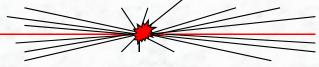

- First physics at the LHC was dominated by large cross section of inelastic hadronic interactions
- Measurements necessary to constrain phenomenological models of soft-hadronic interactions and to predict properties at higher centre-of-mass energies (underlying event, pile-up of minimum bias events at high luminosity,)

Inelastic low - p_T pp collisions

Most interactions are due to interactions at large distance between incoming protons

→ small momentum transfer, particles in the final state have large longitudinal, but small transverse momentum

 $< p_T > \approx 600 \text{ MeV}$

(of charged particles in the final state)

 $\frac{dN}{d\eta} \approx 7$

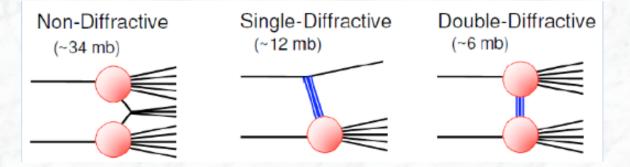

These events are usually referred to as "minimum bias events"

(more precise definition follows)

Total inelastic pp cross section

The total inelastic pp cross section has several components:

Single Diffractive Double Diffractive Non Diffractive

- Use "minimum bias trigger" to study inelastic collisions (an "experimental definition")
- Different definitions can be found in the literature / previous studies:
 (i) Inelastic, non-single diffractive (NSD)

Trigger selection via double-arm coincidence trigger Removal of remaining single-diffractive component, model dependent

(ii) Inelastic, non-diffractive

Removal of single- and double-diffractive components, model dependent

(iii) Inclusive inelastic

Selection via a single-arm trigger, overlapping with the acceptance of the tracking volume

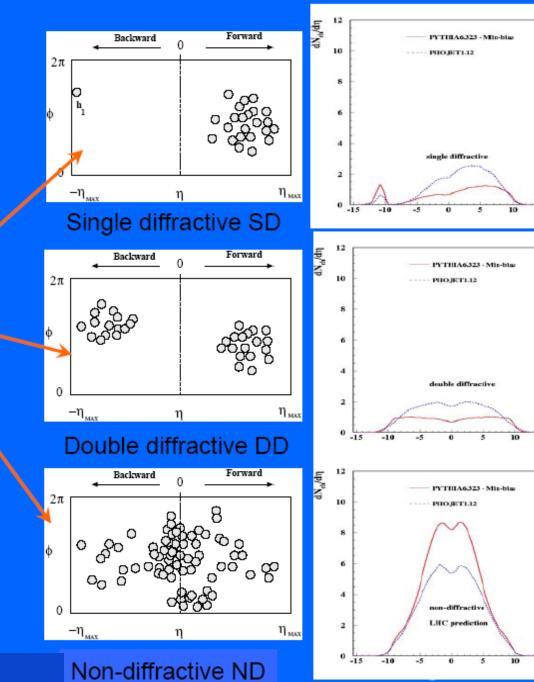

Soft pp collisions

pp collisions at √s = 14TeV	PYTHIA6.323	PHOJET1.12
σ _{tot}	101.5 mb	119.1 mb
σ_{elas}	22.2 mb	34.5mb
2 *σ _{SD}	14.4mb	11.0mb
$\sigma_{ m DD}$	10.3mb	4.1mb
$\sigma_{\rm ND}$	54.7mb	69.5mb

Minimum bias Made up of combination of non-diffractive and diffractive

"Minimum bias events"

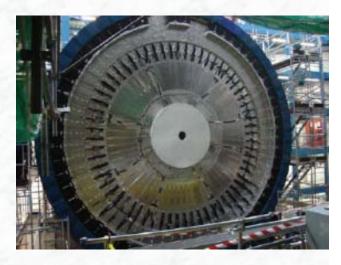

- Minimum bias is an experimental definition, defined by experimental trigger selection and analysis
- Relation to Physics:

η=2.0 interaction point η=3.8 Beam-pipe MBTS

 $\sigma_{\text{measured}} = f_{\text{sd}} \sigma_{\text{sd}} + f_{\text{dd}} \sigma_{\text{dd}} + f_{\text{nd-inelestic}} \sigma_{\text{nd-inelastic}}$

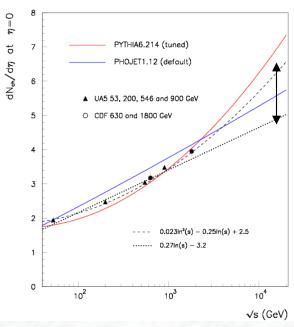

where f_i are the efficiencies for different physics processes determined by the trigger

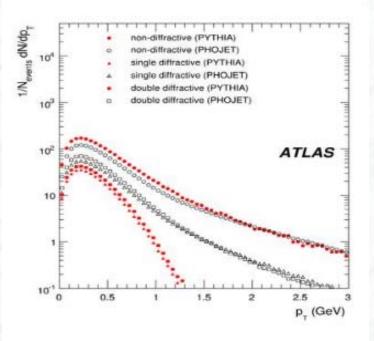

NB: need to understand what is measured to allow comparison to previous results, often presented for non-single diffractive events

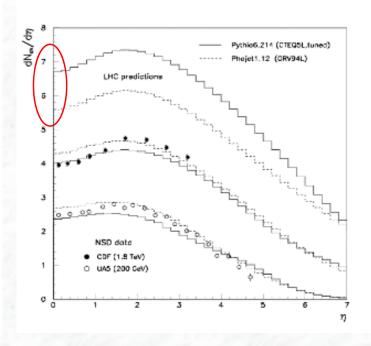

Some features of minimum bias events

- Features of minimum bias events cannot be calculated in perturbative QCD
- Experimental measurements / input needed
- Models / parametrizations were used to extrapolate from previous colliders (energies) to the LHC energy regime → large uncertainties
- Was one of the first physics measurements at the LHC
- Needed to model other interesting physics (superposition of events,...)

<p_T> (η =0): 550 – 640 MeV (15%)

dN_{ch}/dη (η=0): 5-7 (~ 33%)

First measurements from the LHC: datasets and selections

The Event Selection:

MBTS single-cell trigger in coincidence with the BPTX (beam pickup)

➤1 Vertex reconstructed

2 tracks + Beam Spot

>No pileup (secondary vertex with >3 tracks)

Track quality cuts (hits)

cut on the impact parameters at the primary vertex to exclude non primary tracks

<u>Phase Space considered :</u> (see arXiv:1012.5104v2 for more than these two)

Most inclusive ▶≧2 good tracks

 $> p_T > 100 \text{ MeV}$; |η| ≤ 2.5

Lower diffractive contribution

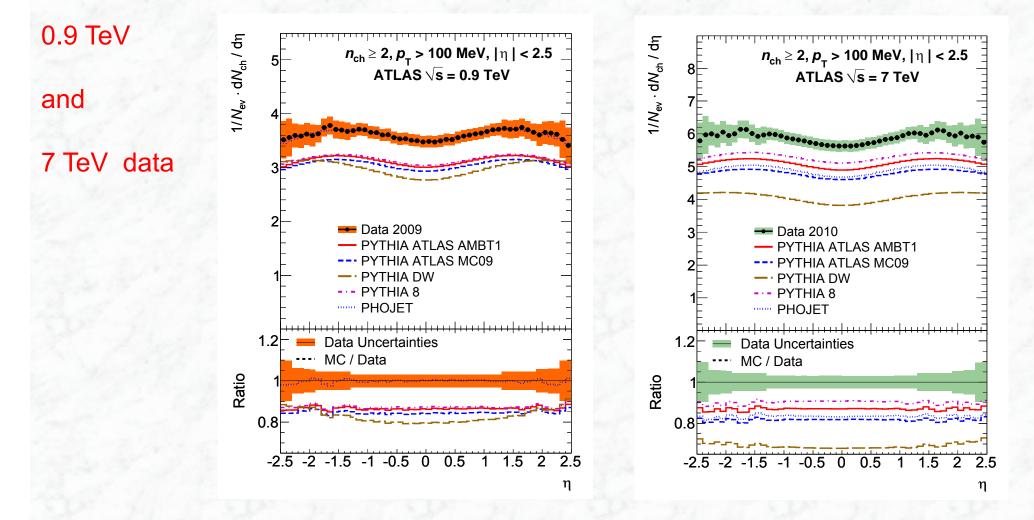

≽≥6 good tracks

 $> p_T > 500$ MeV; |η| ≤ 2.5

Charged particle density versus η

N_{ch}: number of primary charged particles corrected to particle level, normalized to the number of selected events N_{ev}

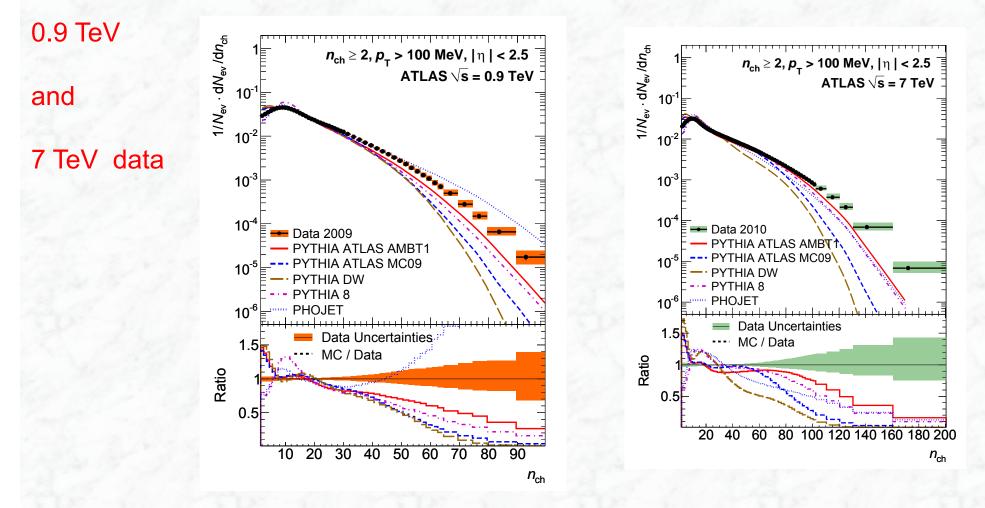

Various Monte Carlo models fail to describe the ATLAS data at both collider energies

Multiplicity distribution of charged particles

 $\mathbf{N_{ch}}:$ number of primary charged particles corrected to particle level, normalized to the number of selected events $\mathbf{N_{ev}}$

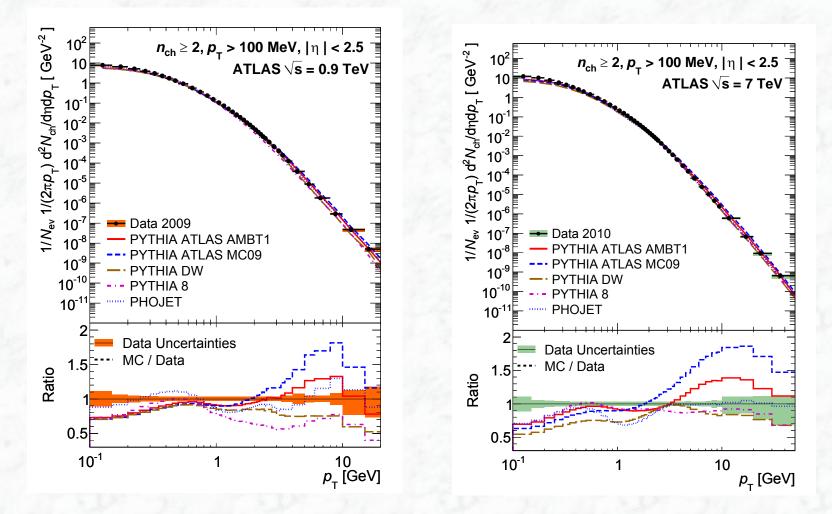

Various Monte Carlo models fail to describe high multiplicity events

Charged particle multiplicities as function of $\ensuremath{p_{T}}$

 $\mathbf{N_{ch}}$: number of primary charged particles corrected to particle level, normalized to the number of selected events $\mathbf{N_{ev}}$

Monte Carlo models also fail to describe the p_T spectrum

The underlying event

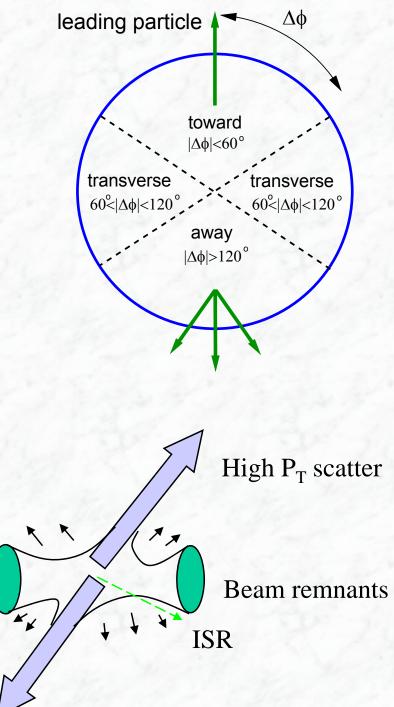

Average charged particle density in transverse region

Extrapolation of the underlying event to LHC energies was unknown;

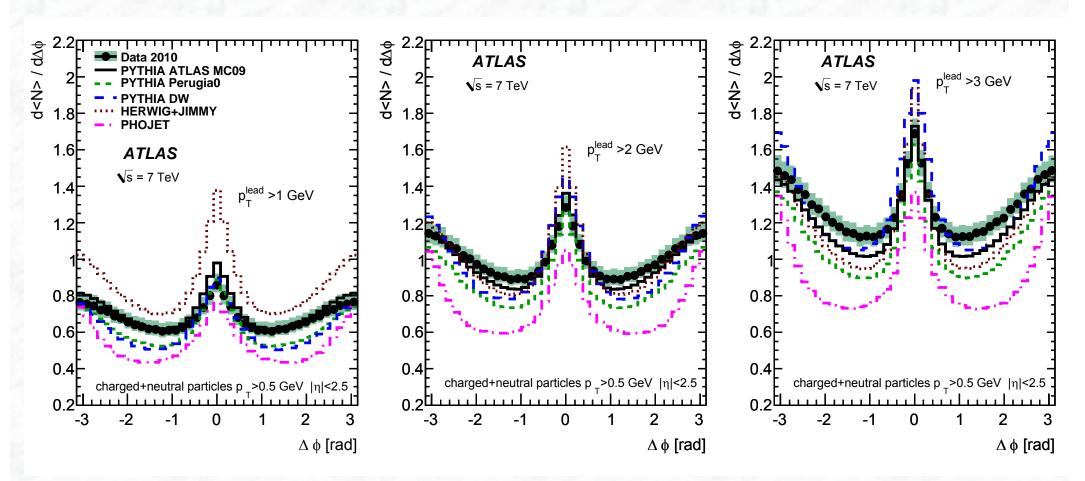

underlying event depends on:

- Multiple interactions
- Radiation
- PDFs
- String formation

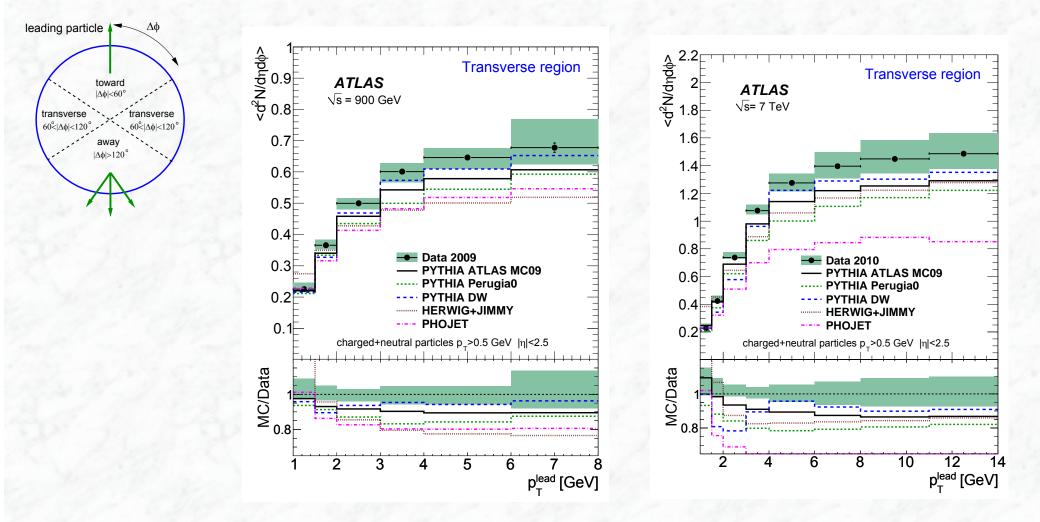

Measurements of underlying event properties with 7 TeV ATLAS data

Measurements of underlying event properties with 7 TeV ATLAS data

- number of particles (charged and neutrals) increase in the transverse region (plateau) by about a factor of two by going from 0.9 TeV to 7 TeV collisions
- models also fail to describe these features
 - ➔ lot of tuning was needed and still needs to be done to parametrize the underlying event models including the necessary correlations
