

## 7.5 What are its properties? Is it the Higgs boson of the Standard Model?

# Is it a Higgs Boson ?

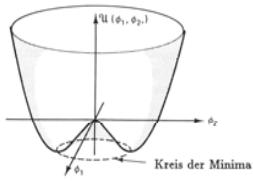

-can the LHC measure its parameters ?-

- Mass
- Couplings to bosons and fermions
- Spin and CP
- Higgs boson width, lifetime ?
- Higgs self coupling

## Motivation:

- After a discovery of a Higgs-boson at the LHC one has to measure its parameters and consolidate that it matches the SM predictions
- As many parameters as possible have to be measured in as many different production and decay channels as possible ! (global fit, see later)
- Discriminate between: SM Higgs boson,  
MSSM like Higgs boson,  
Composite Higgs boson, ....

## Summary: Is it a Higgs Boson ?

### 1. Mass

Higgs boson mass can be measured with high precision  $\ll 1\%$  using  $\gamma\gamma$  and  $ZZ \rightarrow 4\ell$  resonances

### 2. Couplings to bosons and fermions

Ratios of major couplings can be measured with reasonable ( $\sim 10\text{-}30\%$ ) precision;  
Absolute coupling measurements need further theory assumptions

### 3. Spin and CP

Angular correlations are sensitive to spin and CP  
(achievable precision is statistics limited, requires high luminosity)

### 4. Higgs self coupling

No measurement possible at the LHC;  
Very difficult at the HL-LHC

---

---

## Higgs-boson mass

Combine  $H \rightarrow 4l$  and  $H \rightarrow \gamma\gamma$ :

- Full kinematic information in photons and leptons
- Need excellent understanding and calibration of muon, electron, photon momentum scale

New material description in front of the calorimeter

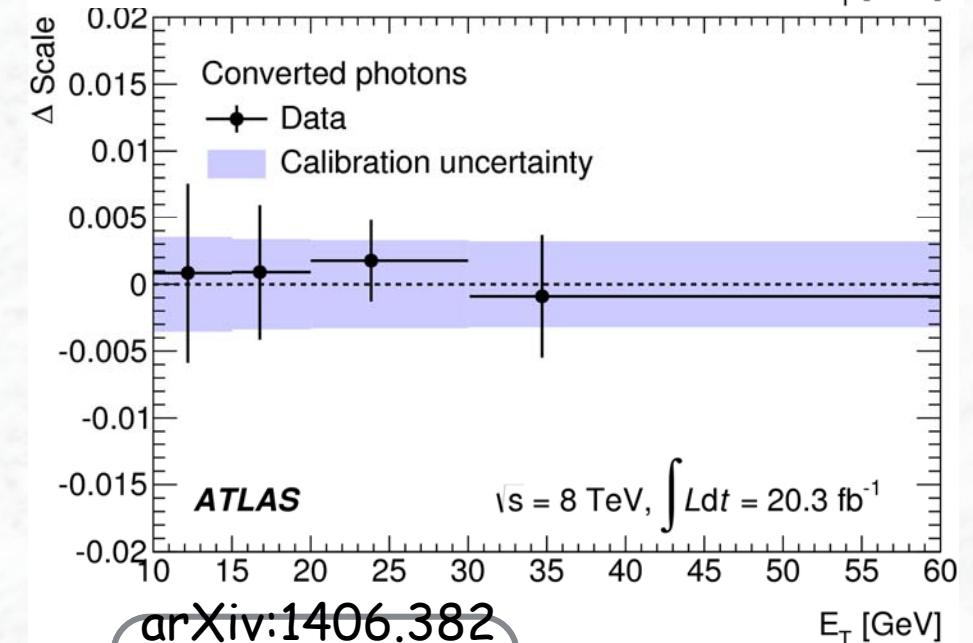

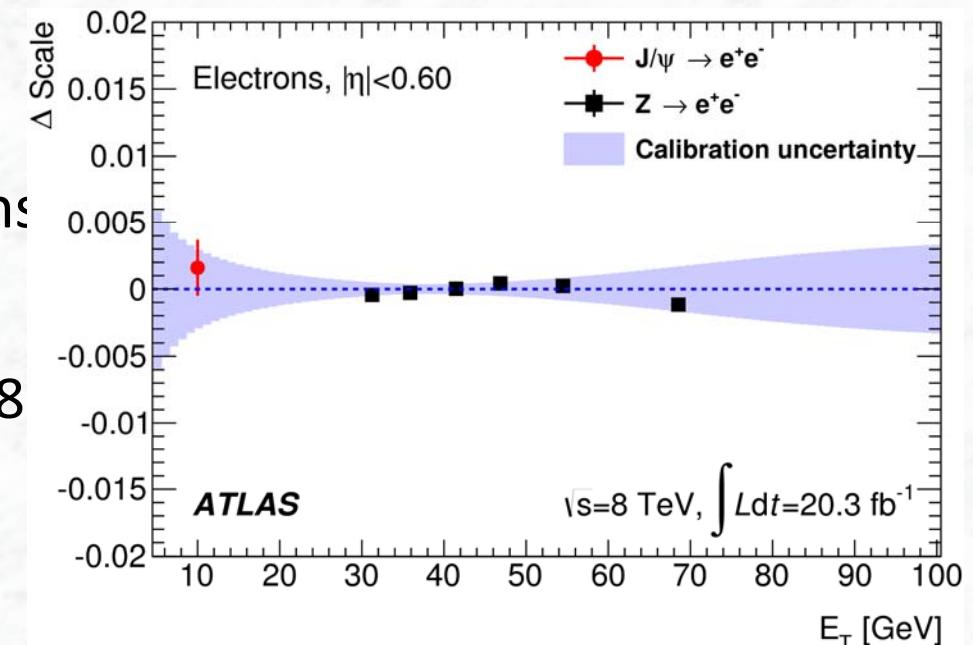

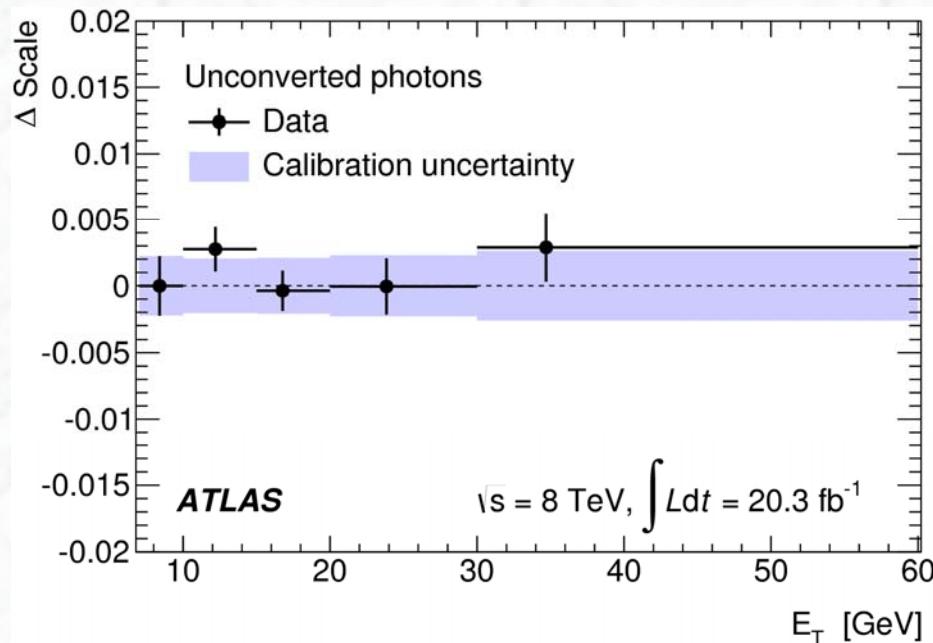

- Determined from detailed analysis of 6.6M  $Z \rightarrow ee(\gamma)$  and 8M  $Z \rightarrow \mu\mu(\gamma)$
- Calibrate individual layers in EM calorimeter with muons, electrons, unconverted photons
- $\Delta X_0/X_0 < 10\%$

Energy response of EM calorimeter

- Very stable vs. time and pileup
- RMS < 0.05%

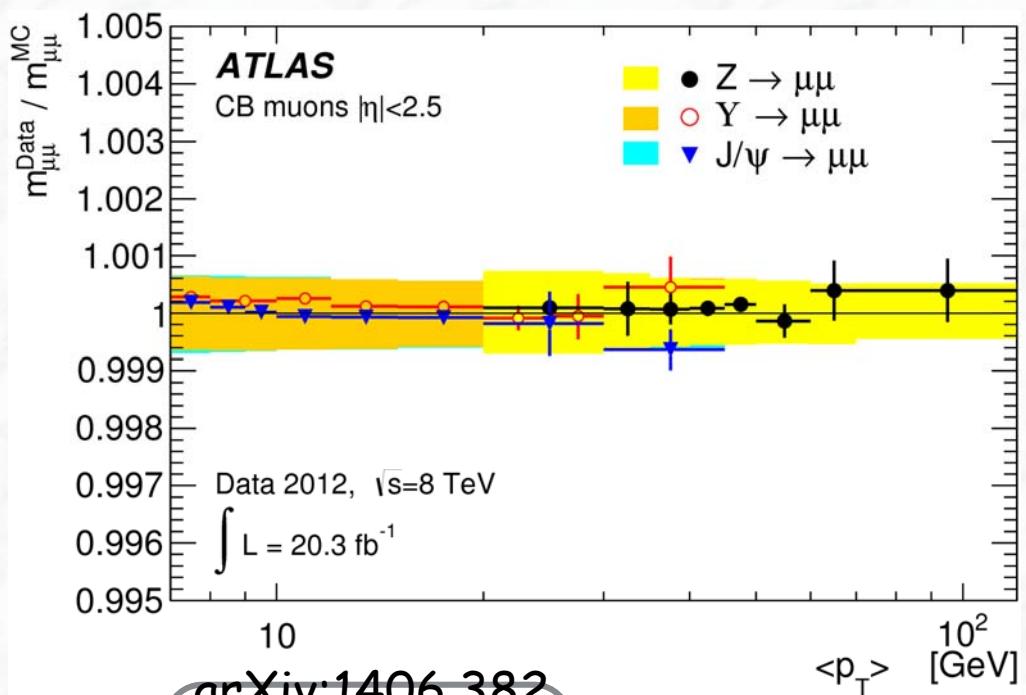

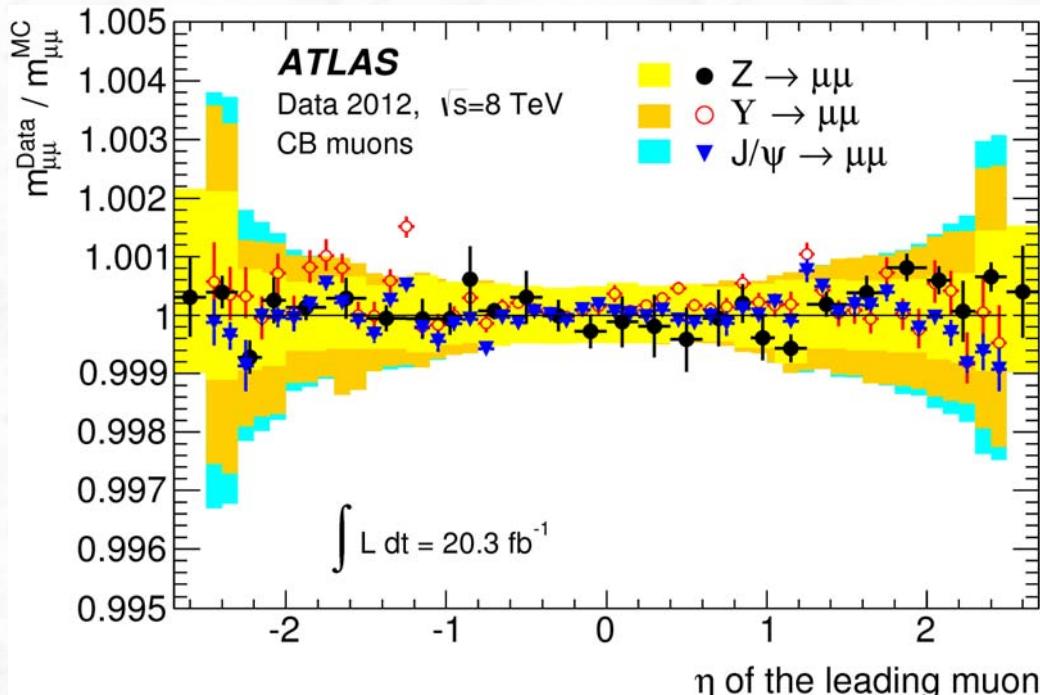

# Electron and Photon Energy Scale

- Systematic uncertainties
- <0.1% to 0.3% for 40 GeV electrons
- For 60 GeV photons:
  - 0.2-0.3% for  $|\eta| < 1.37$  or  $|\eta| > 1.8$
  - ~0.6% for  $1.52 < |\eta| < 1.82$

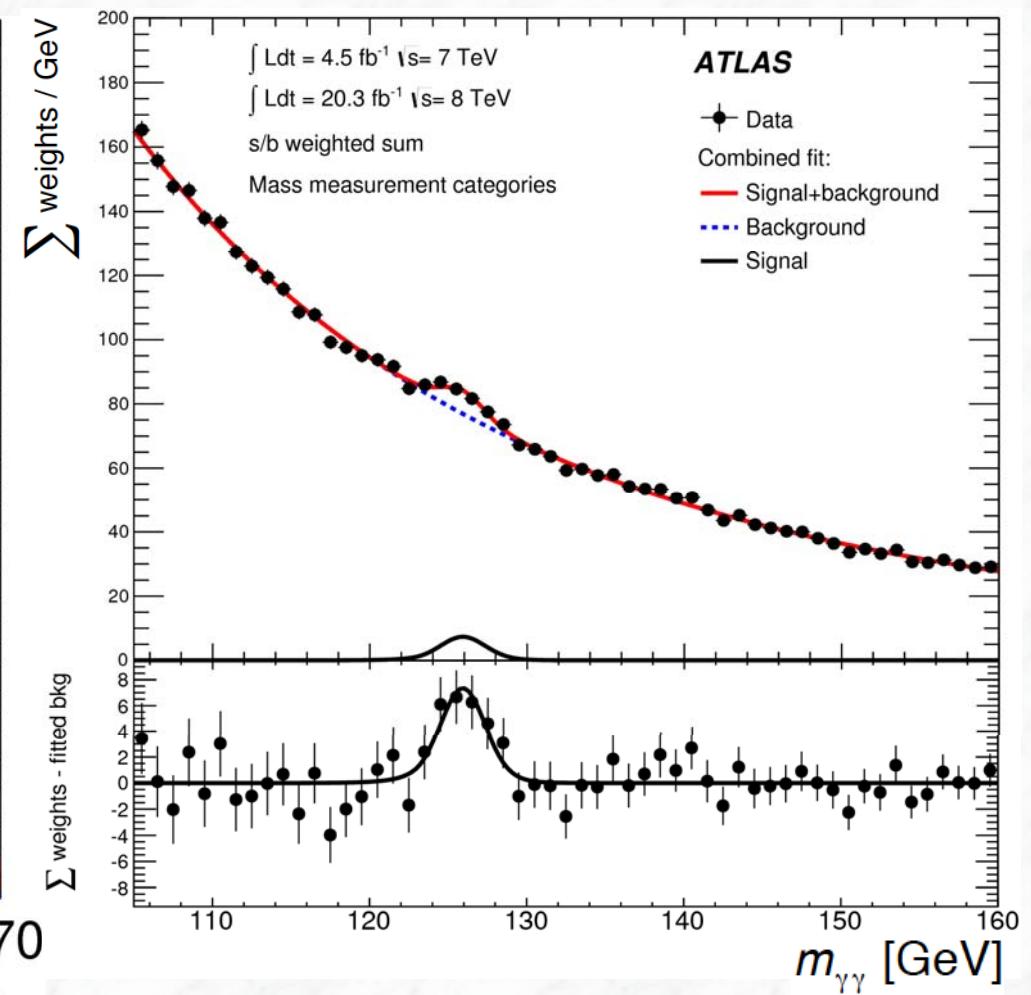

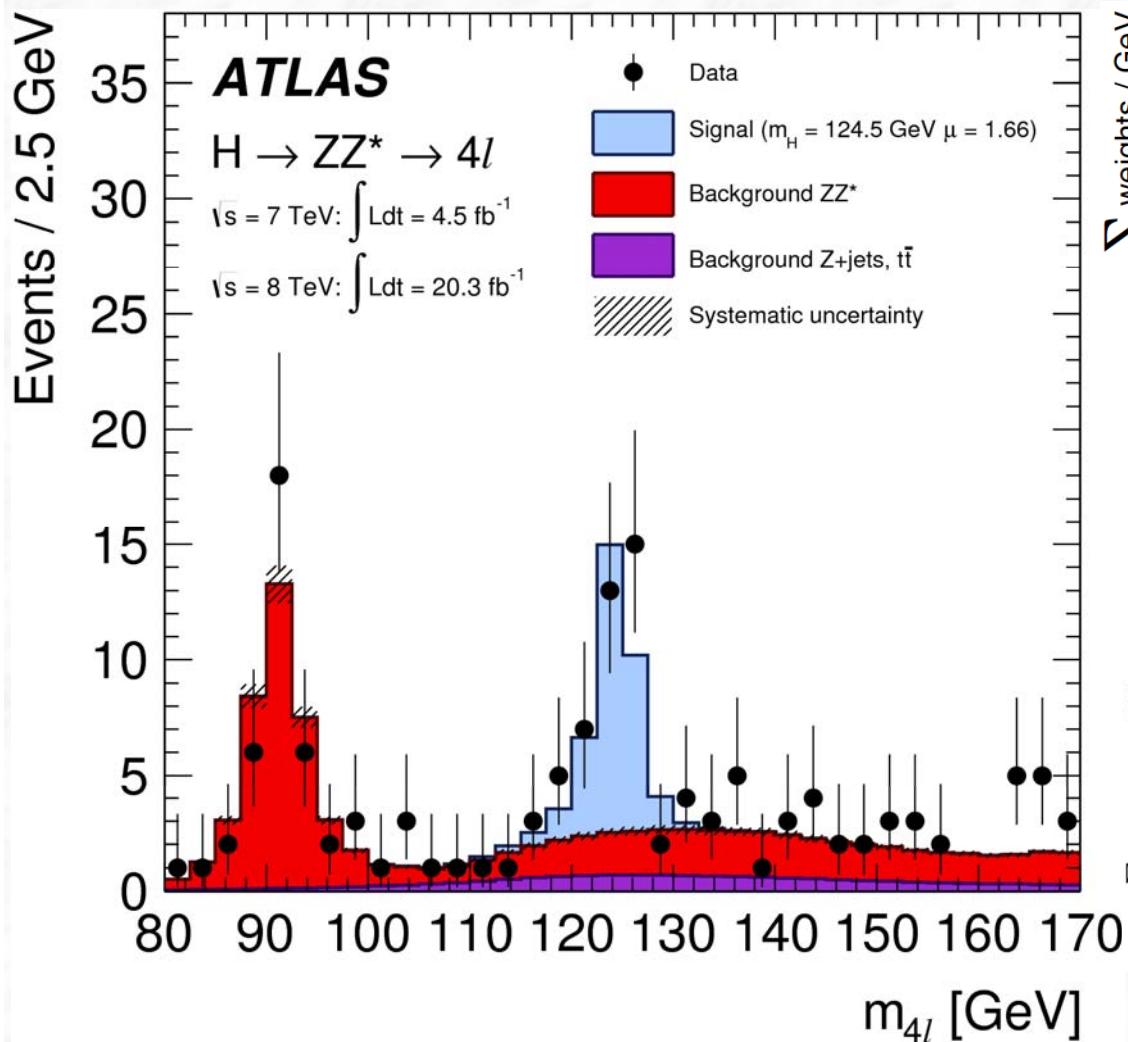

# Muon Momentum Calibration

- New calibration for momentum scale and resolution:
- Combination of two independent measurements (inner tracker and muon spectrometer)
- Using millions of  $Z \rightarrow \mu\mu$ ,  $\Upsilon \rightarrow \mu\mu$ , and  $J/\psi \rightarrow \mu\mu$
- Impact on  $H \rightarrow 4\mu$  mass measurement now  $< 60$  MeV

# Higgs-Boson Mass

- Combination of  $H \rightarrow 4l$  and  $H \rightarrow \gamma\gamma$

# Higgs-Boson Mass

- Systematic uncertainty on combined mass is  $\sim 180$  MeV
  - (compared to  $\sim 540$  MeV in PLB Summer 2013 publication)

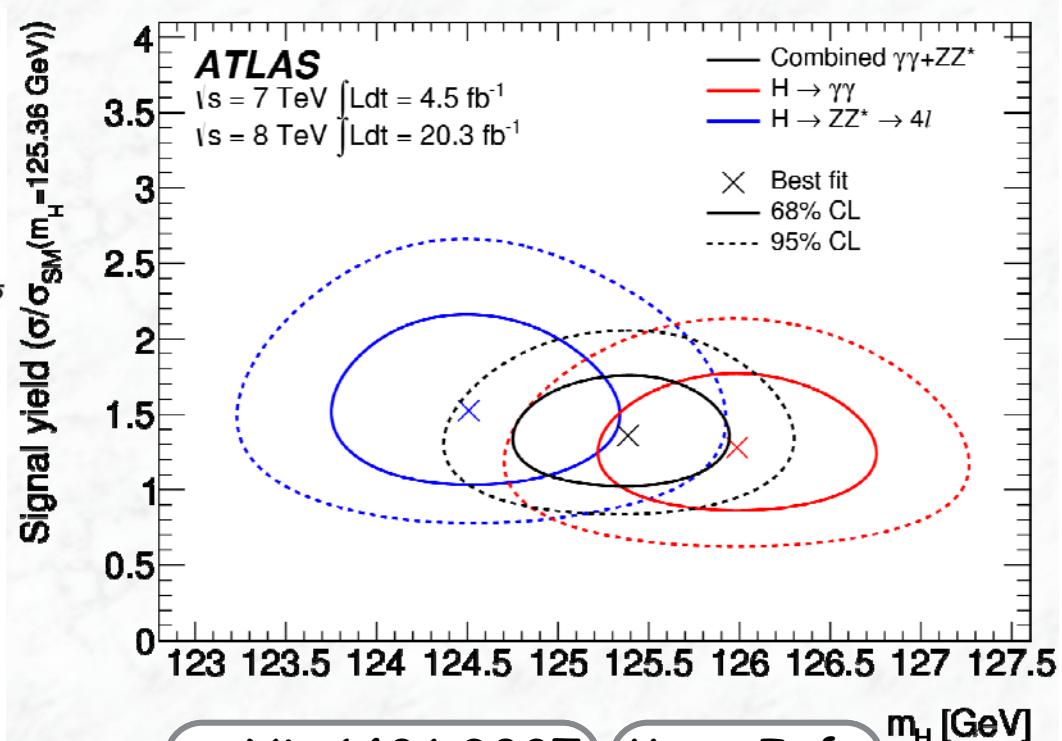

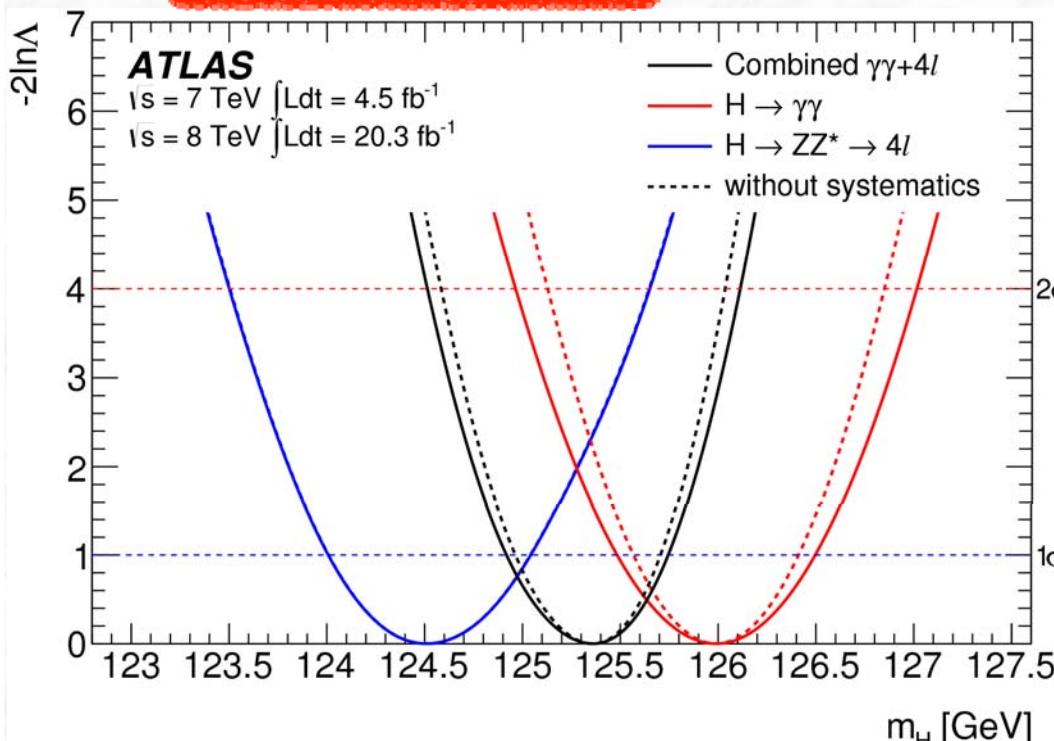

Systematic	Uncertainty on $m_H$ [MeV]
LAr syst on material before presampler (barrel)	70
LAr syst on material after presampler (barrel)	20
LAr cell non-linearity (layer 2)	60
LAr cell non-linearity (layer 1)	30
LAr layer calibration (barrel)	50
Lateral shower shape (conv)	50
Lateral shower shape (unconv)	40
Presampler energy scale (barrel)	20
ID material model ( $ \eta  < 1.1$ )	50
$H \rightarrow \gamma\gamma$ background model (unconv rest low $p_{Tt}$ )	40
$Z \rightarrow ee$ calibration	50
Primary vertex effect on mass scale	20
Muon momentum scale	10
Remaining systematic uncertainties	70
Total	180

# Higgs-Boson Mass

Channel	Mass measurement [GeV]
$H \rightarrow \gamma\gamma$	$125.98 \pm 0.42 \text{ (stat)} \pm 0.28 \text{ (syst)} = 125.98 \pm 0.50$
$H \rightarrow ZZ^* \rightarrow 4\ell$	$124.51 \pm 0.52 \text{ (stat)} \pm 0.06 \text{ (syst)} = 124.51 \pm 0.52$
Combined	$125.36 \pm 0.37 \text{ (stat)} \pm 0.18 \text{ (syst)} = 125.36 \pm 0.41$

$$\Delta m_H = 1.47 \pm 0.67 \text{ (stat)} \pm 0.28 \text{ (sys)} \text{ GeV} = 1.47 \pm 0.72 \text{ GeV}$$

- 2.0 $\sigma$  compatibility (compared to 2.5 $\sigma$  from Summer 2013 publication)

arXiv:1406.3827

# Higgs-boson mass: ATLAS&CMS combination

Combination paper

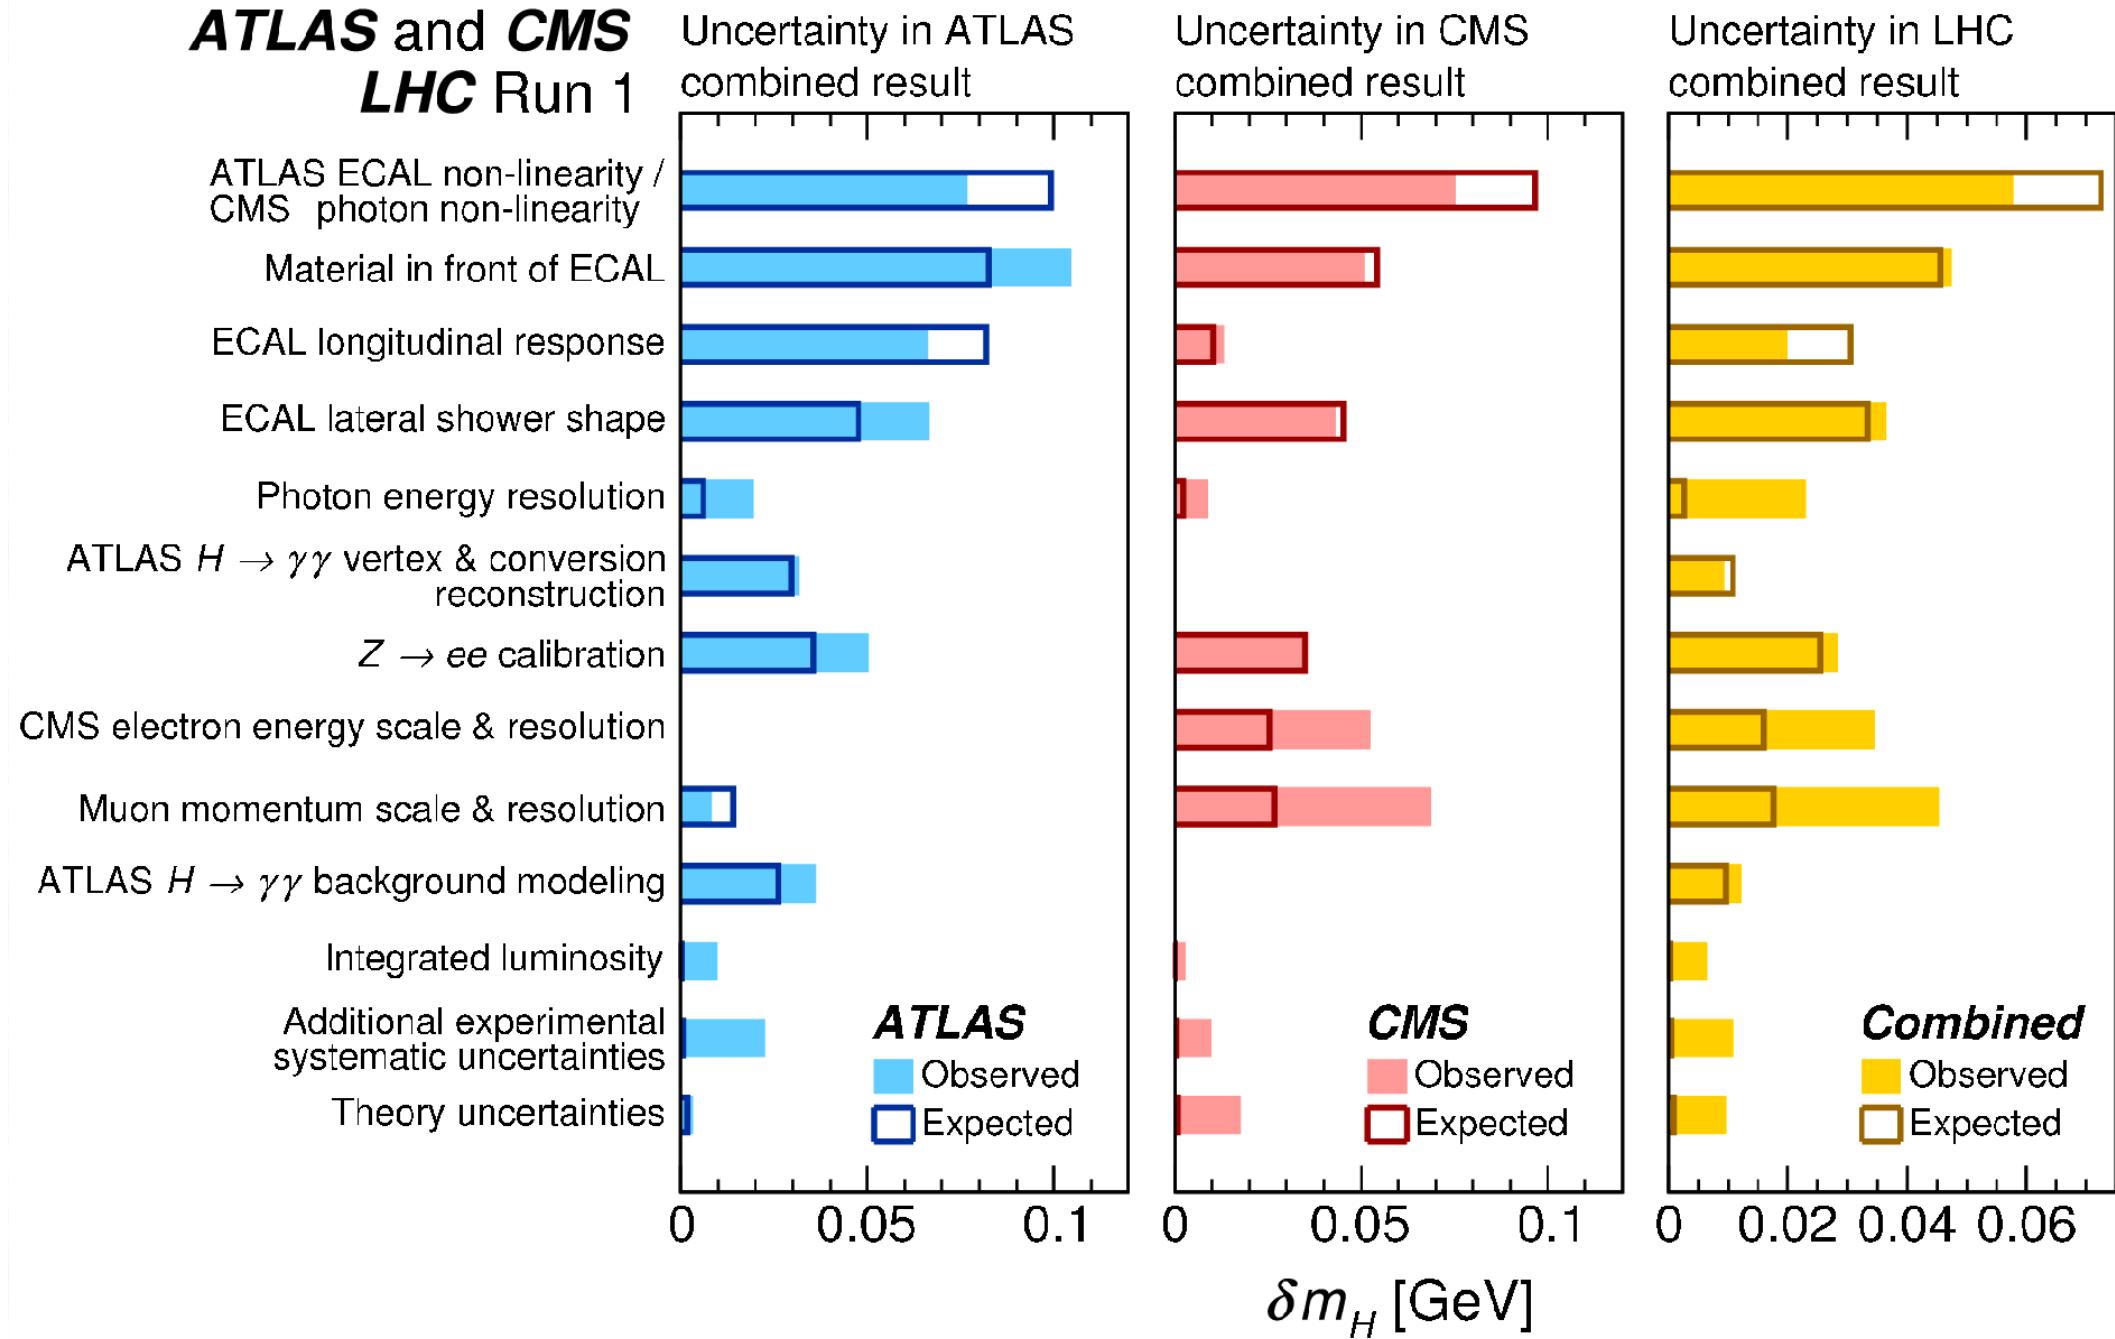

(5154 authors):

<http://arxiv.org/abs/1503.07589>

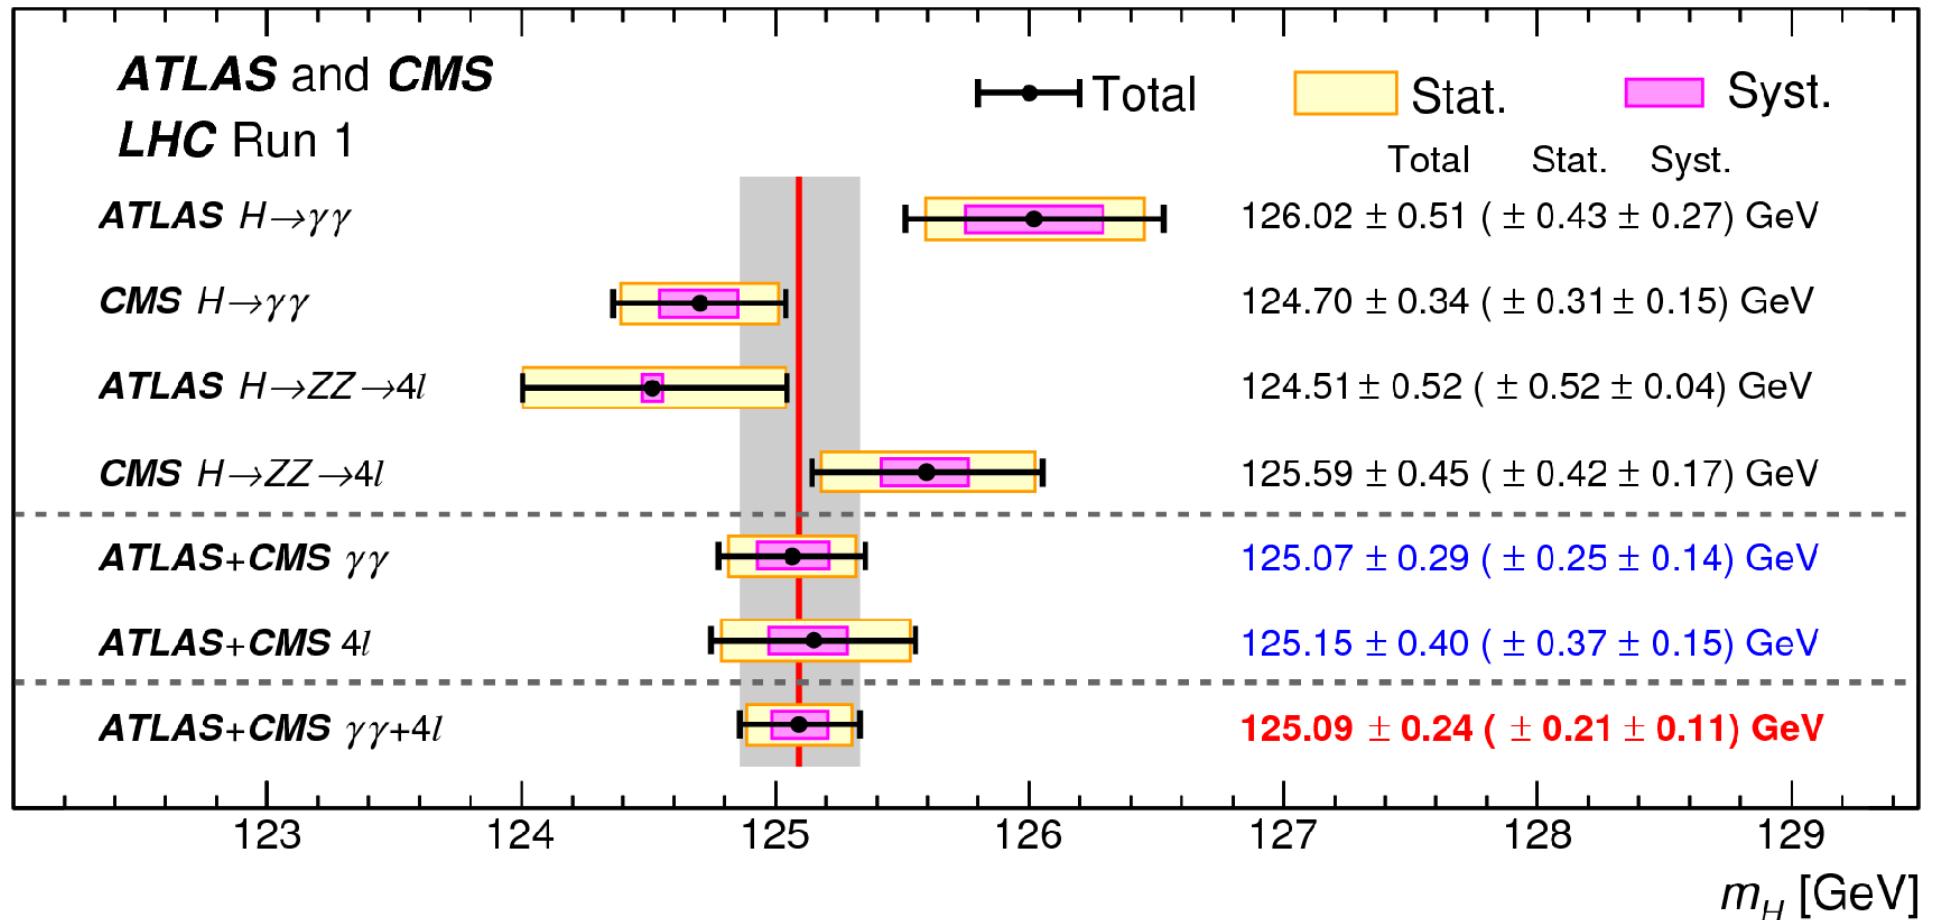

# Higgs-boson mass: ATLAS&CMS combination

## **ATLAS and CMS** **LHC Run 1**

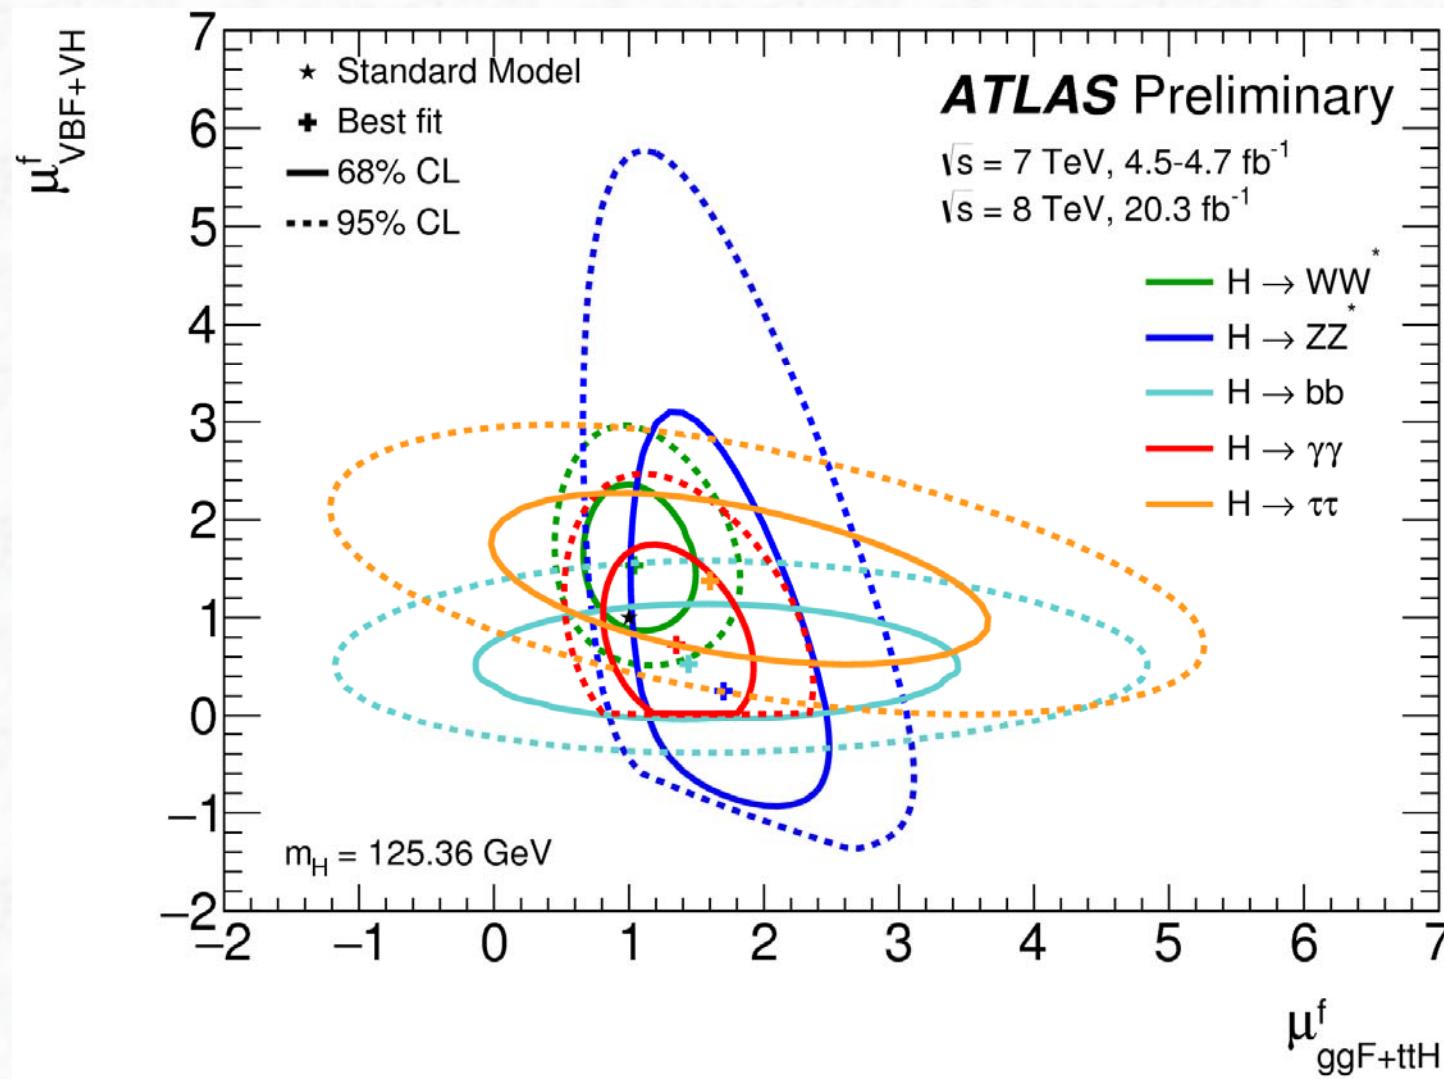

# Higgs-boson mass: ATLAS&CMS combination

# Higgs-boson coupling combination

## Combination framework:

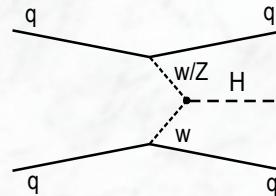

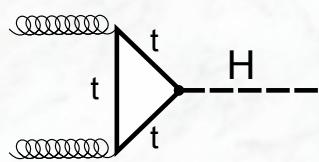

- Use all ATLAS Higgs-boson measurements in one global fit
- Fit for different combinations of parameters of interest

# Higgs boson couplings

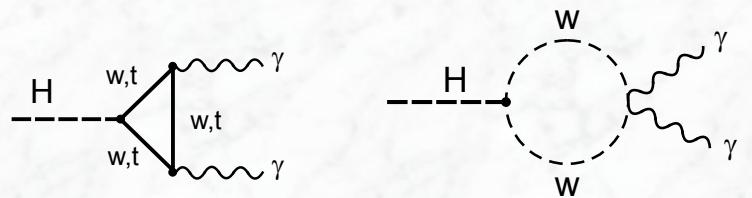

- Production and decay involve several couplings

Production:

Decays: e.g.  $H \rightarrow \gamma\gamma$  (best example)

(Decay widths depends on W and top coupling,  
destructive interference)

- Standard Model couplings are tested by introducing coupling scale factors  $\kappa$

$$g_i = \kappa g_i^{\text{SM}}$$

- Standard Model tree level amplitudes:

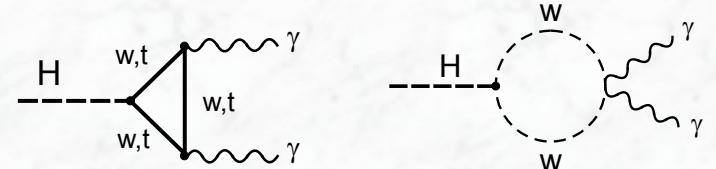

$$\Gamma_{ff} \propto \left( \kappa_f \frac{m_f}{v} \right)^2 = \kappa_f^2 \cdot \Gamma_{ff}^{\text{SM}}$$

$$\Gamma_{VV} \propto \left( \kappa_f \frac{m_V^2}{v} \right)^2 = \kappa_V^2 \cdot \Gamma_{VV}^{\text{SM}}$$

# Higgs boson couplings

- Example:  $H \rightarrow \gamma\gamma$

$$\Gamma_{\gamma\gamma} \propto |1.28\kappa_W - 0.28\kappa_t|^2 \cdot \Gamma_{\gamma\gamma}^{\text{SM}}$$

- Loop scaling factors can be expressed in terms of  $\kappa_f$  and  $\kappa_v$
- The analysis is also done in terms of **effective loop couplings**  $\kappa_g$  and  $\kappa_\gamma$

# Higgs boson couplings

- Benchmarks defined by LHC cross section working group (leading-order tree-level framework):
  - Signals observed originate from a single resonance;  
(mass assumed here is 125.5 GeV)
  - Narrow width approximation: → rates for given channels can be decomposed as:

$$\sigma \cdot B(i \rightarrow H \rightarrow f) = \frac{\sigma_i \cdot \Gamma_f}{\Gamma_H}$$

$i, f$  = initial, final state  
 $\Gamma_f, \Gamma_H$  = partial, total width

- Modifications to coupling strength are considered (coupling scale factors  $\kappa$ ), tensor structure of Lagrangian assumed as in Standard Model

# Scaling of cross sections with $\kappa_F$ and $\kappa_V$ factors

$$\sigma \cdot \text{BR}(\text{gg} \rightarrow H \rightarrow \gamma\gamma) = \sigma_{\text{SM}}(\text{gg} \rightarrow H) \cdot \text{BR}_{\text{SM}}(H \rightarrow \gamma\gamma) \cdot \frac{\kappa_g^2 \cdot \kappa_\gamma^2}{\kappa_H^2}$$

$$\sigma(gg \rightarrow H) * \text{BR}(H \rightarrow \gamma\gamma) \sim \frac{\kappa_F^2 \cdot \kappa_\gamma^2(\kappa_F, \kappa_V)}{0.75 \cdot \kappa_F^2 + 0.25 \cdot \kappa_V^2}$$

$$\sigma(qq' \rightarrow qq'H) * \text{BR}(H \rightarrow \gamma\gamma) \sim \frac{\kappa_V^2 \cdot \kappa_\gamma^2(\kappa_F, \kappa_V)}{0.75 \cdot \kappa_F^2 + 0.25 \cdot \kappa_V^2}$$

$$\sigma(gg \rightarrow H) * \text{BR}(H \rightarrow ZZ^{(*)}, H \rightarrow WW^{(*)}) \sim \frac{\kappa_F^2 \cdot \kappa_V^2}{0.75 \cdot \kappa_F^2 + 0.25 \cdot \kappa_V^2}$$

$$\sigma(qq' \rightarrow qq'H) * \text{BR}(H \rightarrow ZZ^{(*)}, H \rightarrow WW^{(*)}) \sim \frac{\kappa_V^2 \cdot \kappa_V^2}{0.75 \cdot \kappa_F^2 + 0.25 \cdot \kappa_V^2}$$

$$\sigma(qq' \rightarrow qq'H, VH) * \text{BR}(H \rightarrow \tau\tau, H \rightarrow b\bar{b}) \sim \frac{\kappa_V^2 \cdot \kappa_F^2}{0.75 \cdot \kappa_F^2 + 0.25 \cdot \kappa_V^2}$$

## (i) Couplings to fermions and bosons

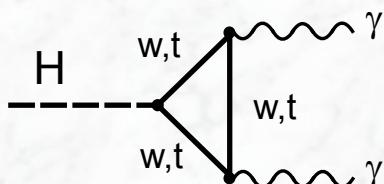

- Assume only one scale factor for fermion and vector couplings:

$$\kappa_V = \kappa_W = \kappa_Z$$

$$\kappa_F = \kappa_t = \kappa_b = \kappa_\tau$$

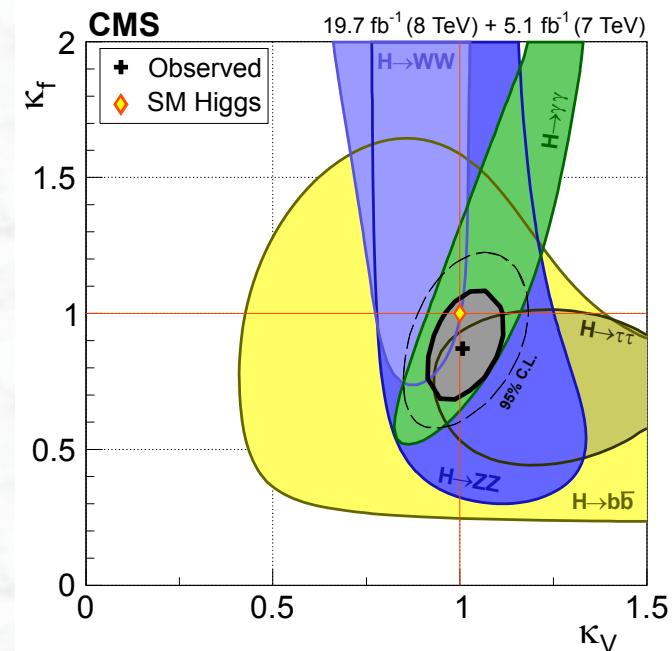

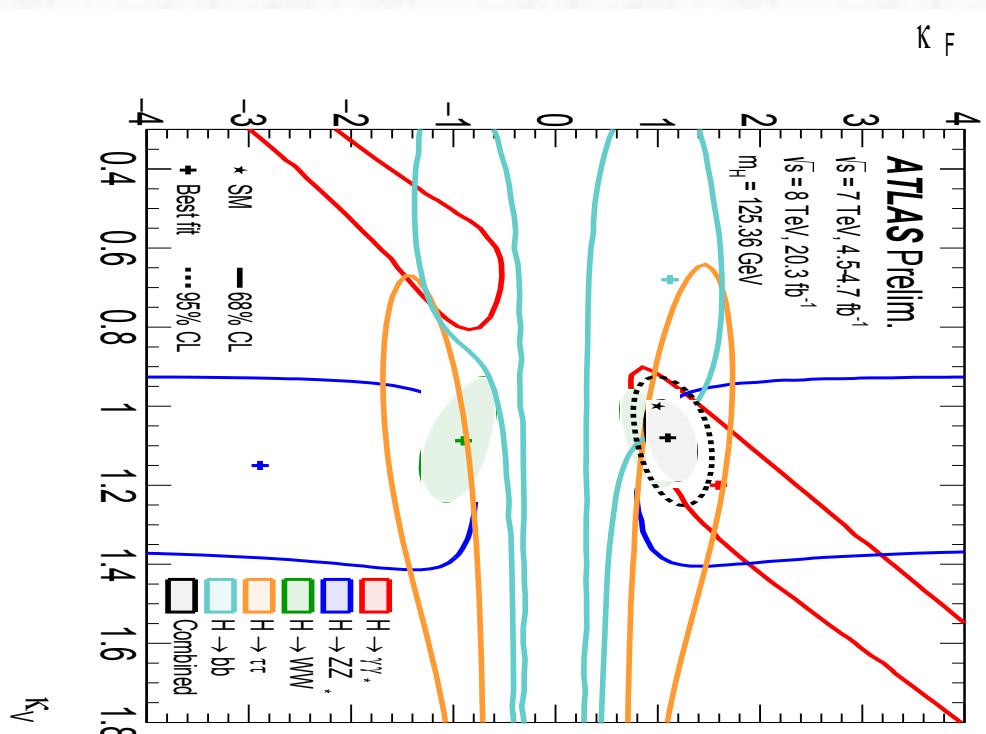

The size of the current data set is insufficient to quantify all parameters

- Assume that  $H \rightarrow \gamma\gamma$  and  $gg \rightarrow H$  loops and the total Higgs boson width depend only on  $\kappa_V$  and  $\kappa_F$   
(no contributions from physics beyond the Standard Model)
- Sensitivity to relative sign between  $\kappa_F$  and  $\kappa_V$  only from interference term in  $H \rightarrow \gamma\gamma$  decays (assume  $\kappa_V > 0$ )

## (i) Couplings to fermions and bosons (cont.).

Results: Data are consistent with the SM expectation;

Fit results:  $k_V = 1.09 \pm 0.07$   
 $k_F = 1.11 \pm 0.16$

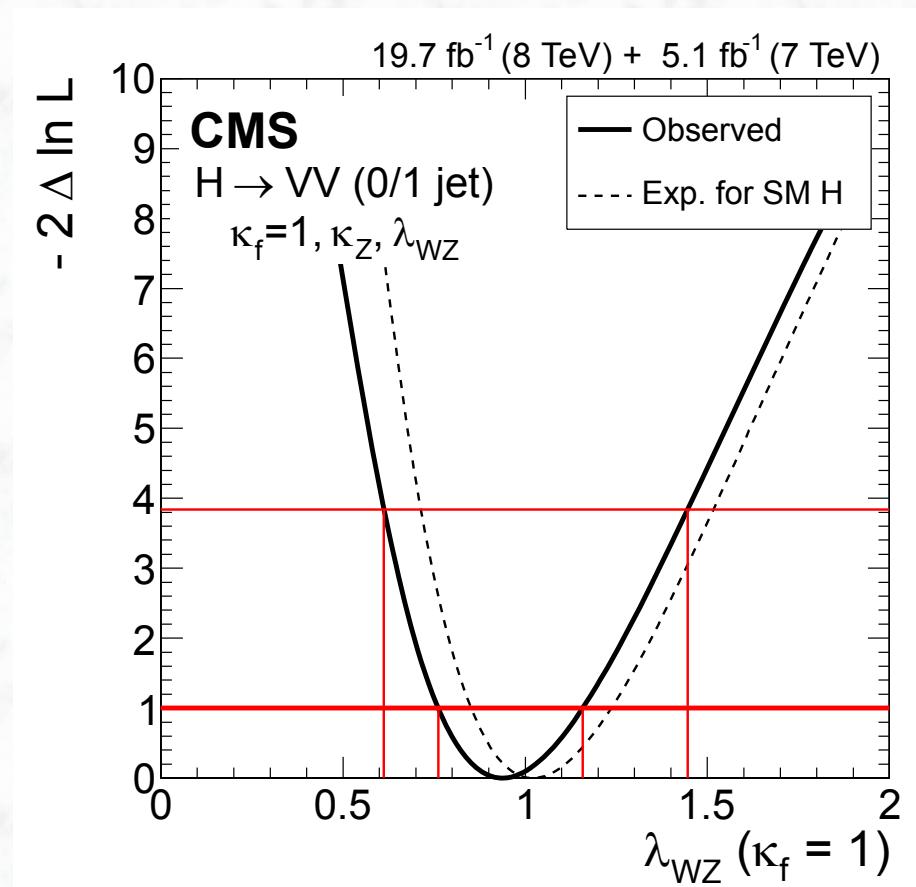

Fit results:  $k_V \in [0.87, 1.14]$  (95% CL)  
 $k_F \in [0.63, 1.15]$  (95% CL)

## (ii) Ratio of couplings to the W and Z bosons

- Relation between  $m_W$  and  $m_Z$  in the Standard Model requires  $\lambda_{WZ} := \kappa_W / \kappa_Z = 1$  ( $\rho$  parameter required to be 1)
- Sensitivity via VBF and VH production and  $H \rightarrow WW$  and  $H \rightarrow ZZ$  rates

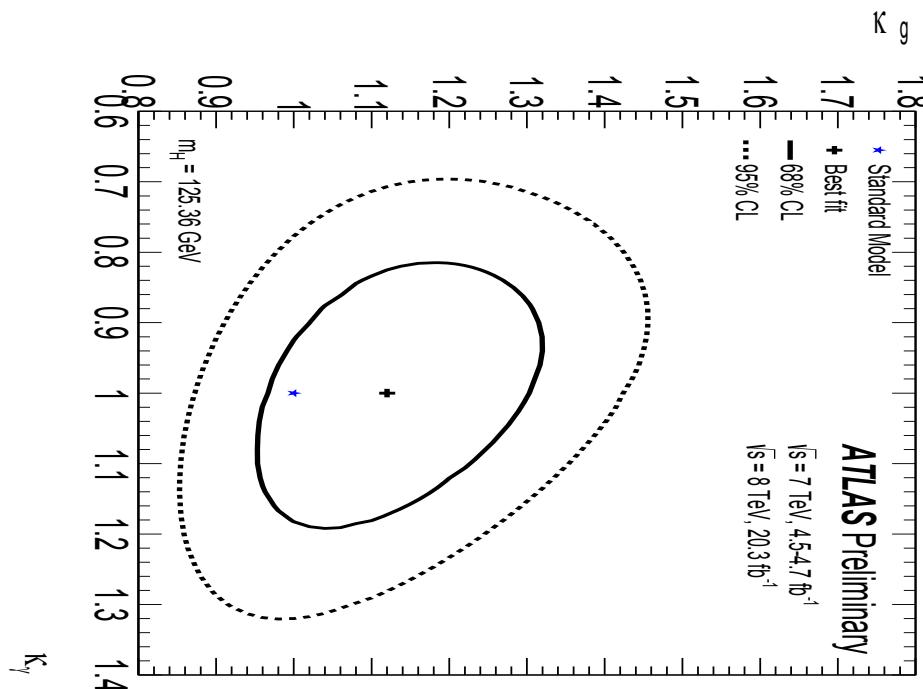

Data are consistent with  
 $\lambda_{WZ} := \kappa_W / \kappa_Z = 1$

### (iii) Constraints on production and decay loops

- Test on contributions from other particles contributing to loop-induced processes
- Assume nominal couplings for all SM particles  $\kappa_i = 1$  and that the new particles do not contribute to the Higgs boson width
- Fit for effective scale factors  $\kappa_g$  and  $\kappa_\gamma$

Best fit values:  $k_\gamma = 1.00 \pm 0.12$   
(ATLAS)       $k_g = 1.12 \pm 0.12$

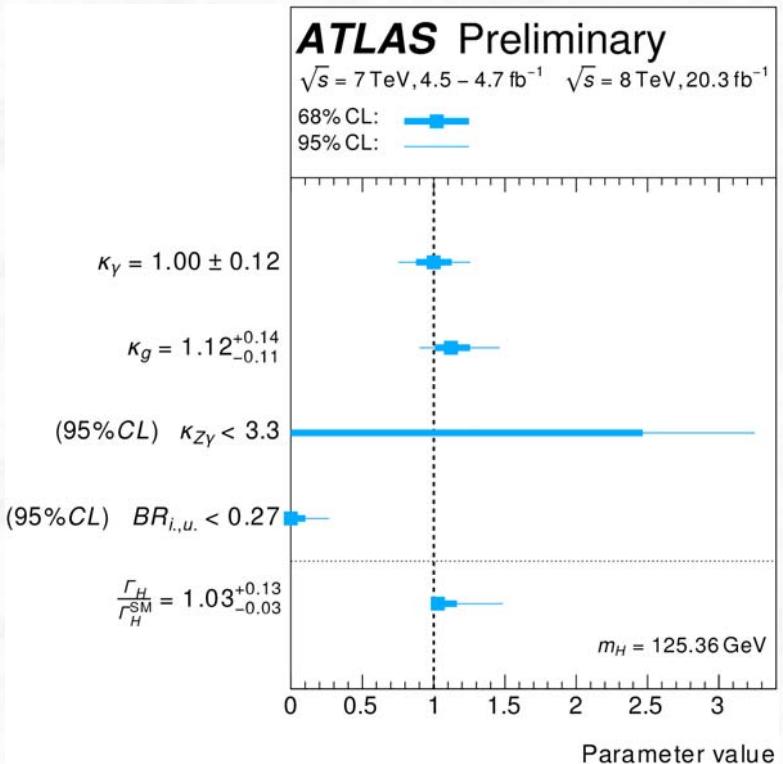

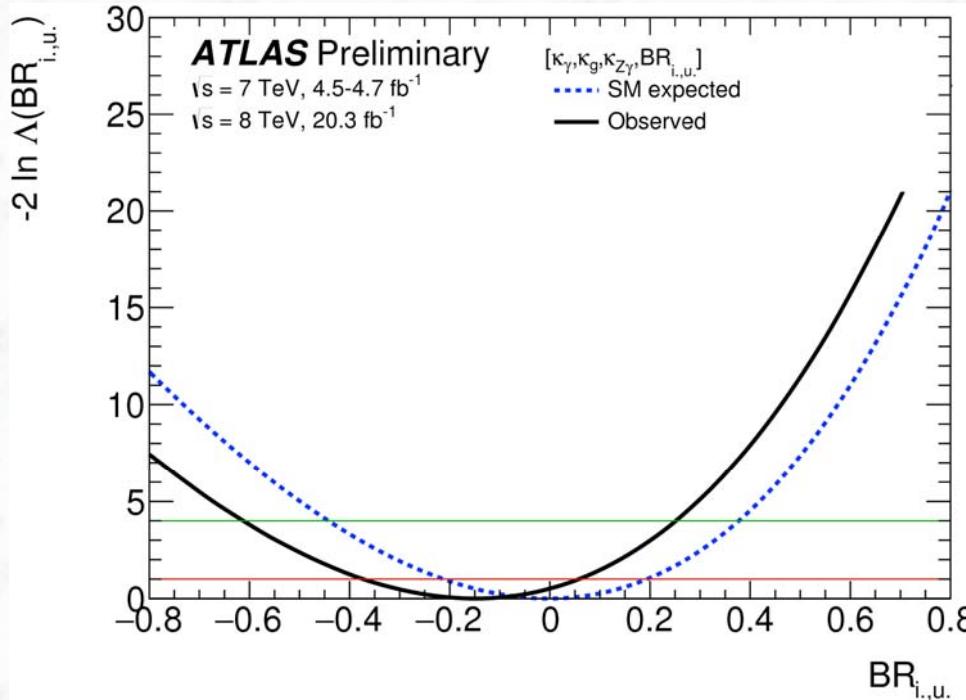

## (iv) Constraints on invisible decays ( $\text{BR}_{\text{BSM}}$ )

- There might be invisible decays that would increase the total decay width:
- $\Gamma_H = \Gamma_{\text{SM}} + \Gamma_{\text{BSM}}$       ( $\text{BR}_{\text{BSM}} = \Gamma_{\text{BSM}} / \Gamma_H$ )

Assume nominal couplings for all SM  
particle  $\kappa_i = 1$   
Three fitted parameters:  $k_g$ ,  $k_\gamma$  and  $\text{BR}_{\text{BSM}}$

$\text{BR}_{\text{BSM}} < 0.27$  (95% CL)

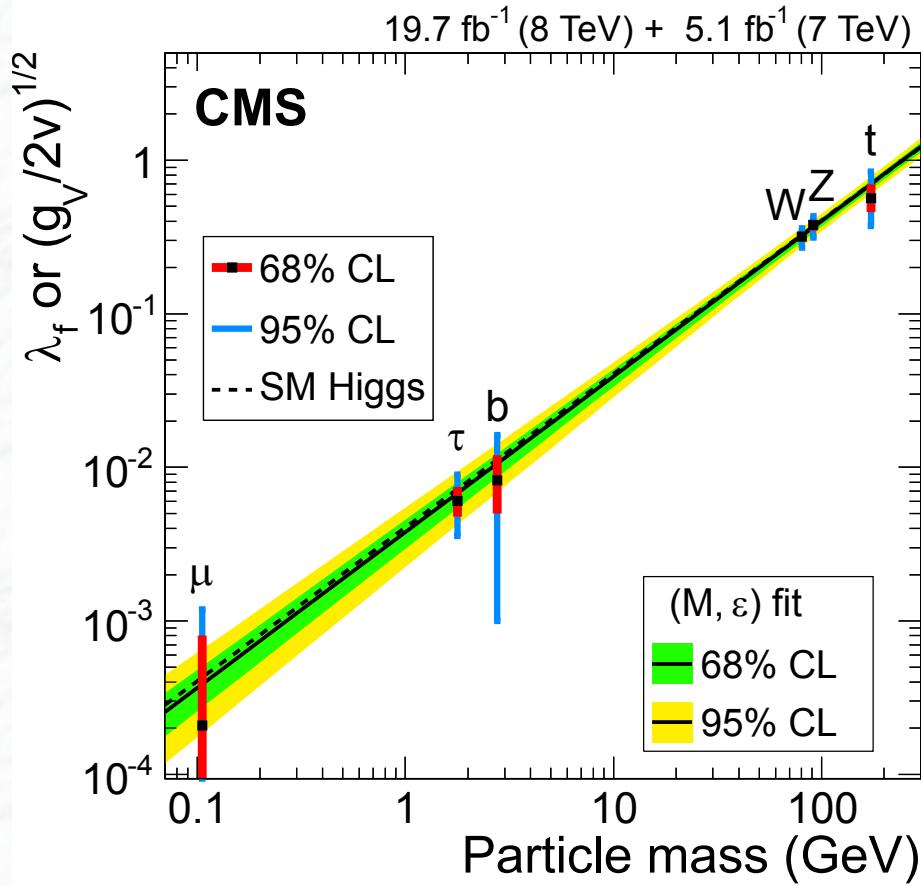

# Higgs boson couplings

- Fit all coupling scale factors for relevant particles ( $W, Z, t, b, \tau, \mu$ ) independently;
- Loop factors expressed in terms of these scale factors, assume SM particle content

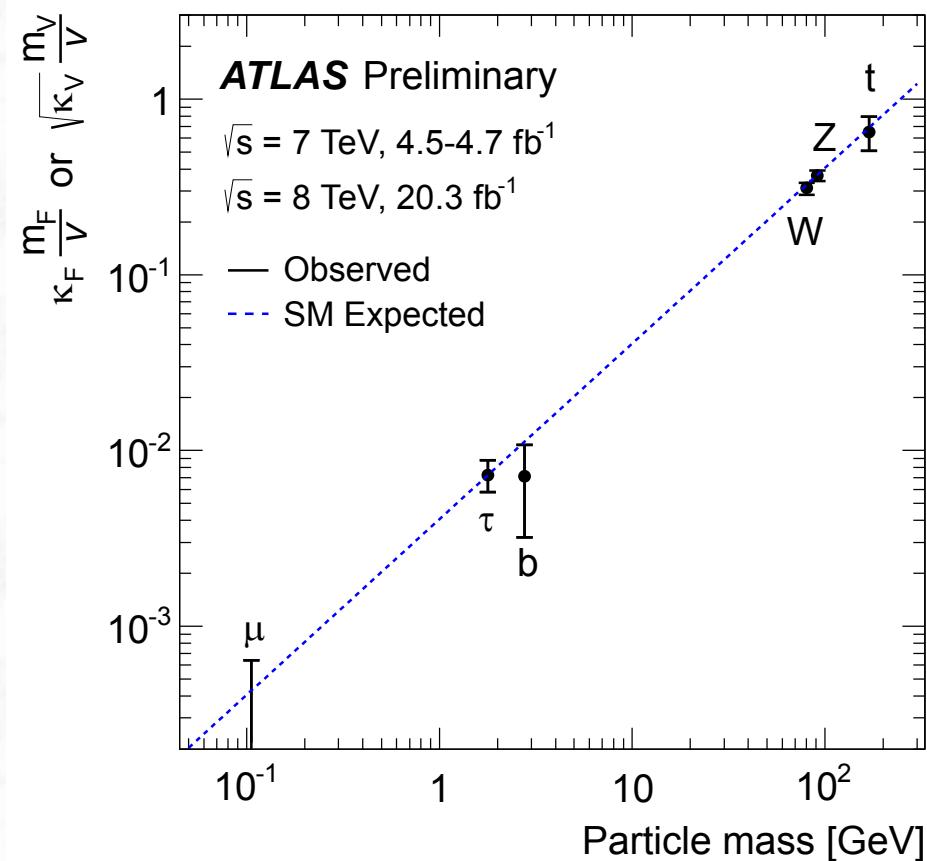

$\lambda_f$  = Yukawa coupling for fermions  
 $\sqrt{g/2v}$  = couplings for  $W/Z$  bosons

EPJ C75 (2015) 5, 212

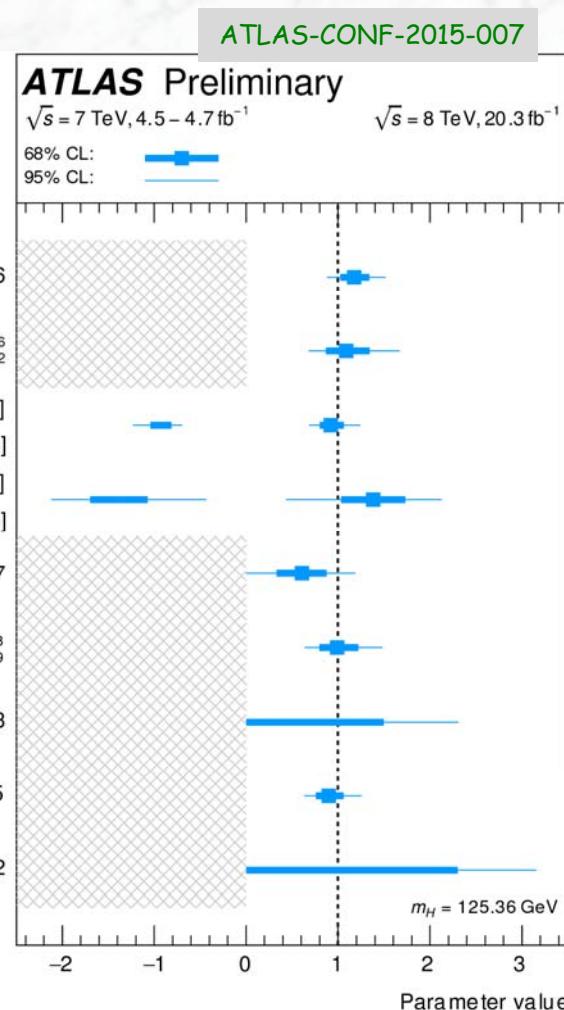

ATLAS-CONF-2015-007

For the first time, non-universal, mass-dependent couplings observed

# Ratios of Higgs boson couplings (model independent)

- In the most general model, only ratios of couplings can be measured independently on any assumptions on the total width (allowing also deviations in vertex loop coupling strength)

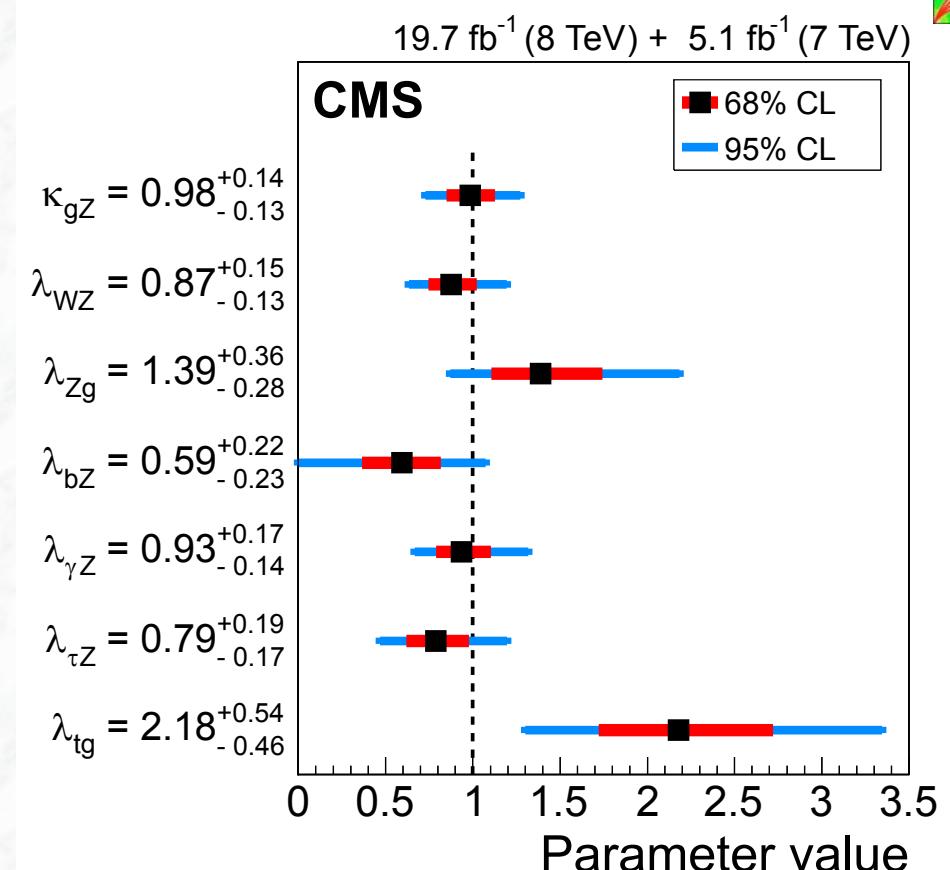

$\lambda_{WZ}$ : test of custodial symmetry

$\lambda_{\gamma Z}$ : sensitive to new charged particles in  $H \rightarrow \gamma\gamma$  loop  
w.r.t  $H \rightarrow ZZ$  decays

$\lambda_{tg}$ : sensitive to new coloured particles contributing to  
 $gg \rightarrow H$  production w.r.t.  $ttH$  production

**EPJ C75 (2015) 5, 212**

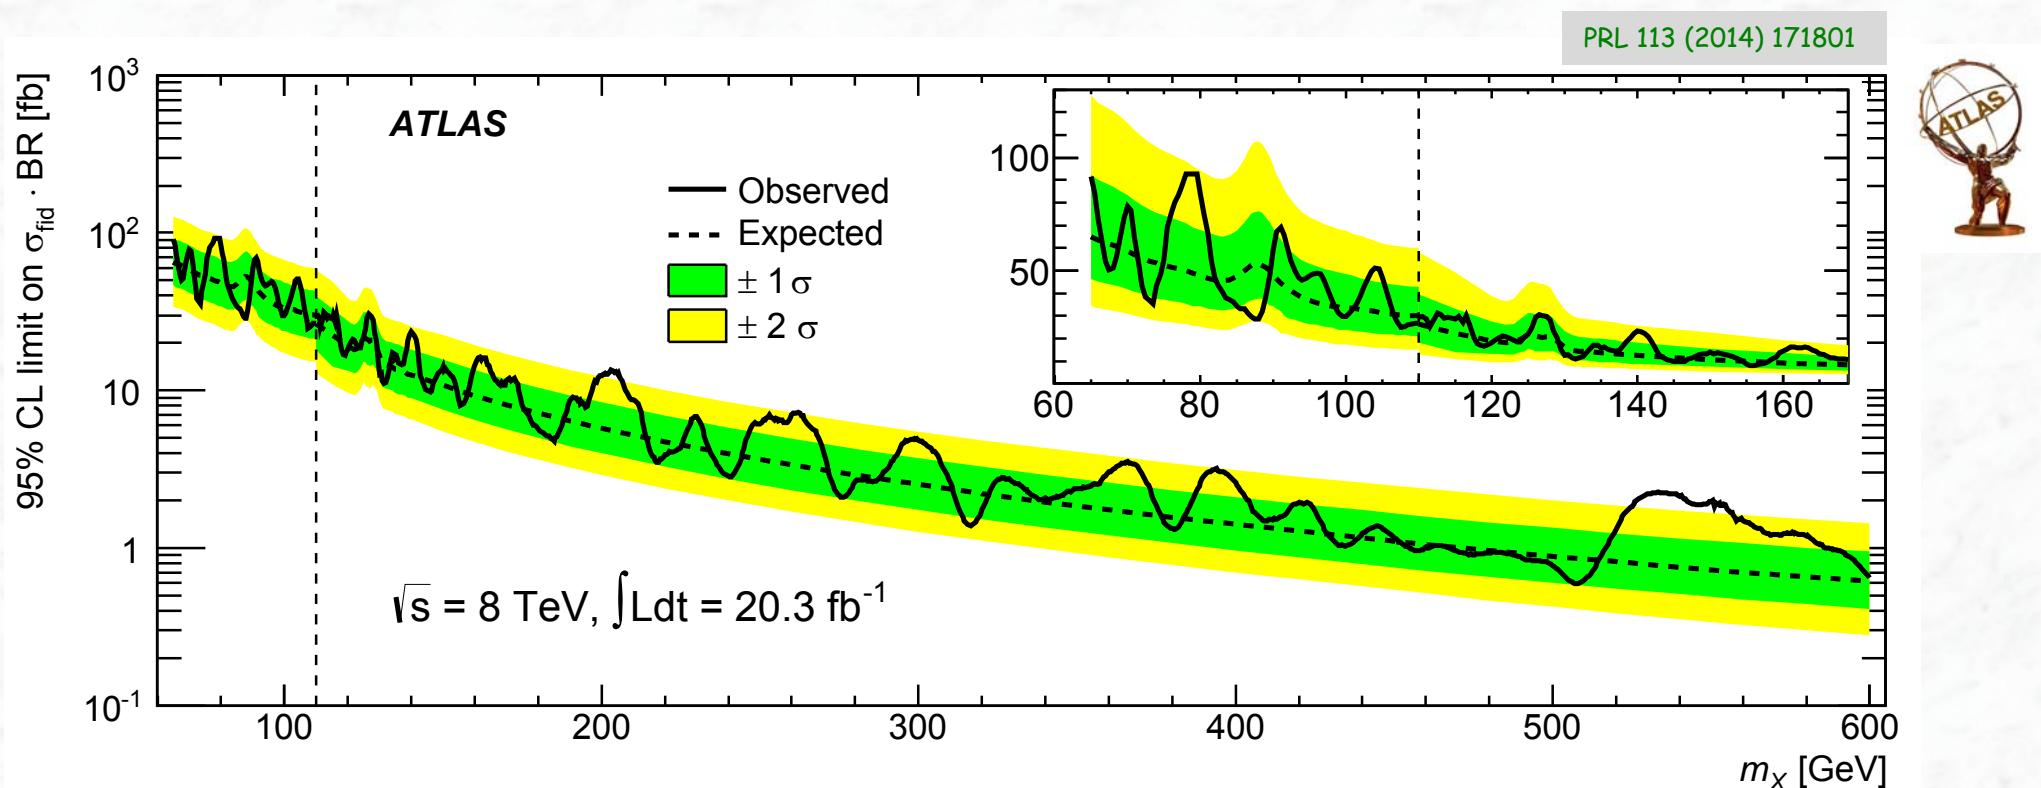

Good consistency with the  
Standard Model Higgs boson  
hypothesis

# Search for Additional Higgs Bosons

## -a few examples-

(i) Results of an ATLAS search on additional resonances X decaying into  $\gamma\gamma$

Observed and expected 95% CL limits on the fiducial cross section times branching ration  $\text{BR}(X \rightarrow \gamma\gamma)$  as a function of mass

(note: 125 GeV signal was treated as “background” and contribution was subtracted)

# Outlook towards Run 2

## Expectations from LHC:

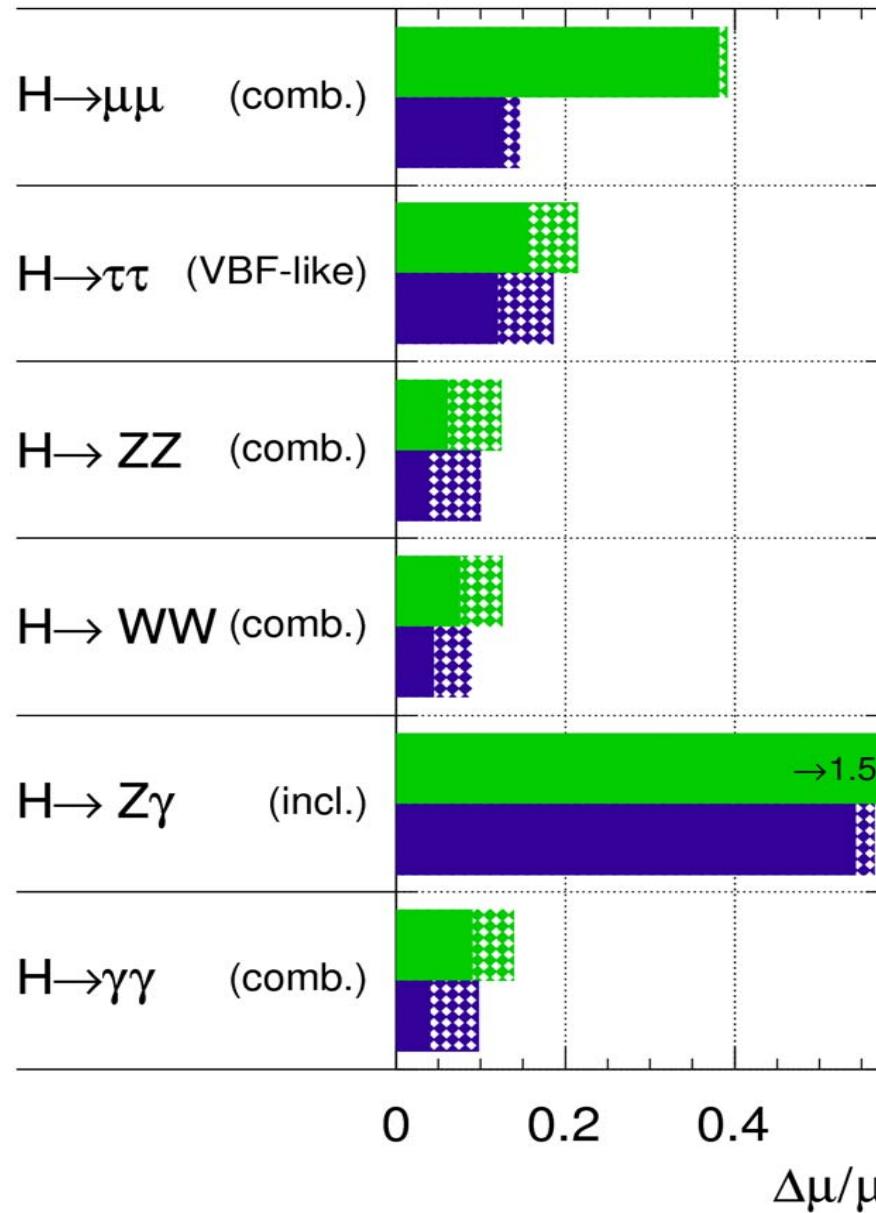

- $\sim 100 \text{ fb}^{-1}$  at 13-14 TeV
  - ⇒ Expect 10 times more Higgs-bosons compared to Run 1

## Consequences for Higgs boson parameter extractions:

- $\kappa$ -framework has shortcomings:
  - Neglects completely tensor structure of coupling operators
  - Strictly only interpretable for  $\kappa=1$
- New approach: Effective Field Theory  $\mathcal{L}_{eff} = \mathcal{L}_{SM}^{(4)} + \sum_i \frac{1}{\Lambda^{d_i-4}} c_i \mathcal{O}_i$ 
  - Full tensor structure
  - Use Spin-CP measurements in the same framework
  - Can take differential measurements into account
  - Interpretable for all values of the parameters to high precision

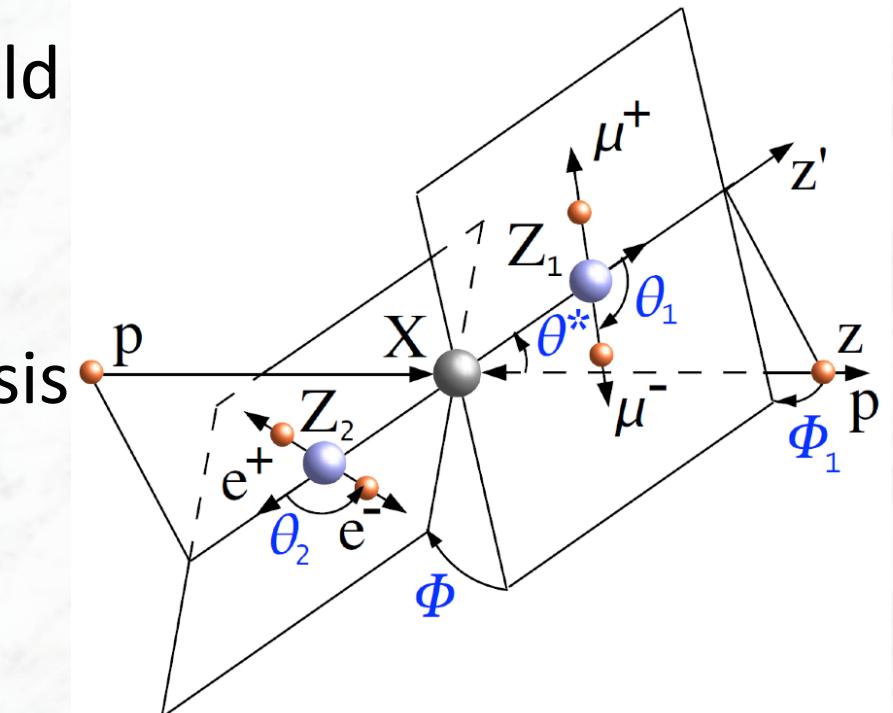

# Outlook towards HL-LHC

**ATLAS** Simulation Preliminary  
 $\sqrt{s} = 14 \text{ TeV}$ :  $\int L dt = 300 \text{ fb}^{-1}$  ;  $\int L dt = 3000 \text{ fb}^{-1}$

# Spin and Parity

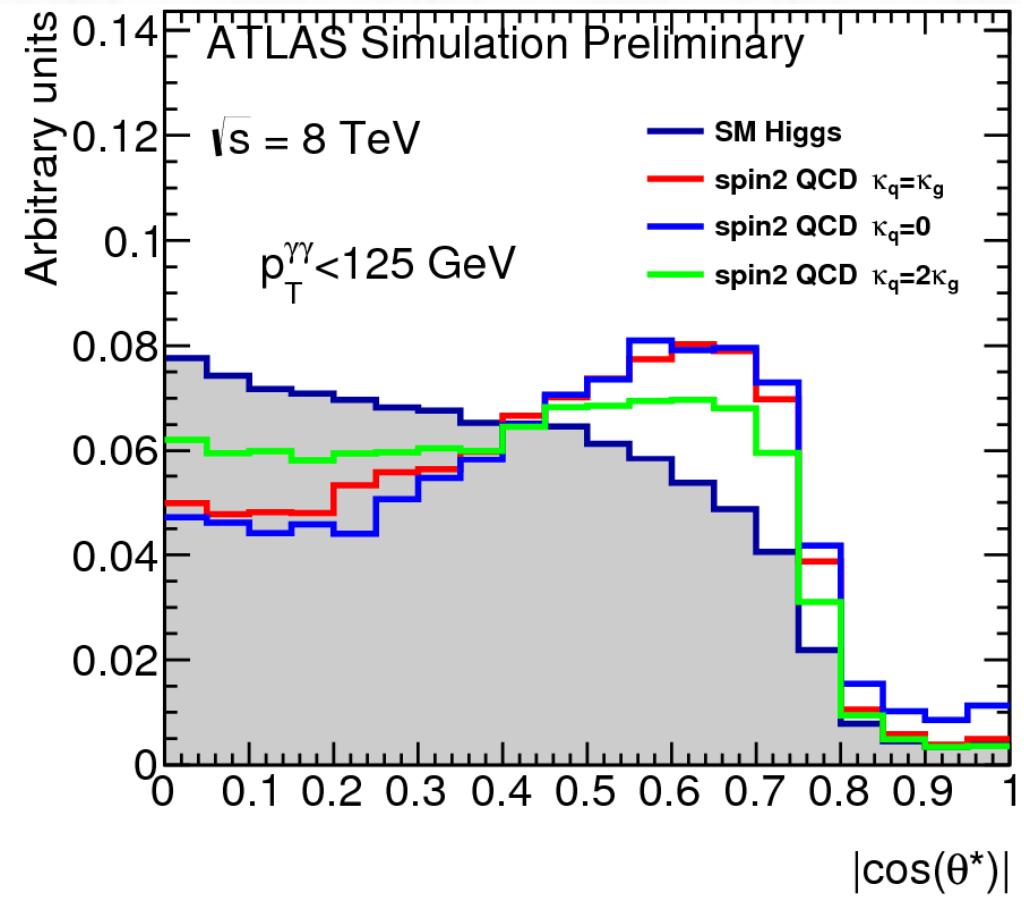

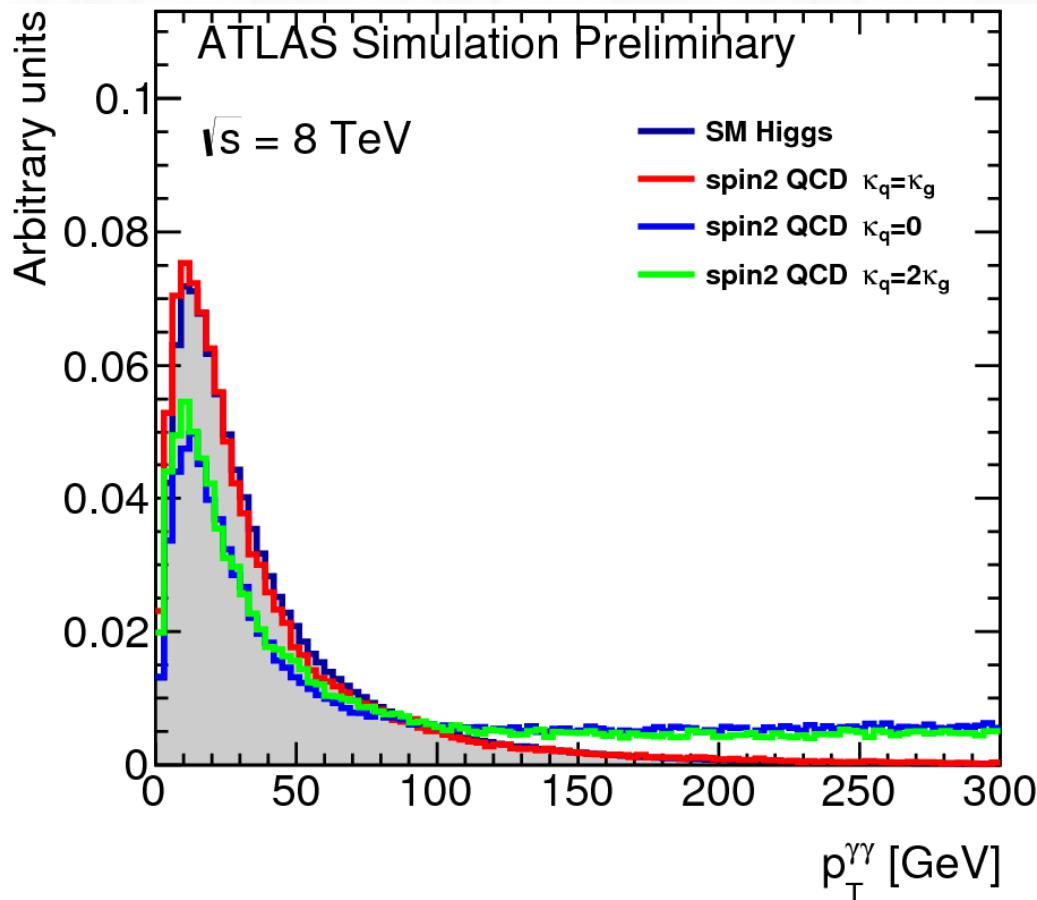

- Standard Model Higgs boson:  $J^P = 0^+$ 
  - Strategy is to *falsify other hypothesis* ( $0^-$ ,  $1^+$ ,  $1^-$ ,  $2^+$ ,  $2^-$ ) and *demonstrate consistency with SM  $0^+$  hypothesis*
  - Spin 1 already strongly disfavoured by observed  $H \rightarrow \gamma\gamma$  and Landau-Yang theorem
  - Use angular variables and build a combined discriminant
  - Calculate likelihood ratio between alternative hypothesis and standard  $0^+$  hypothesis

# Spin und CP

## General:

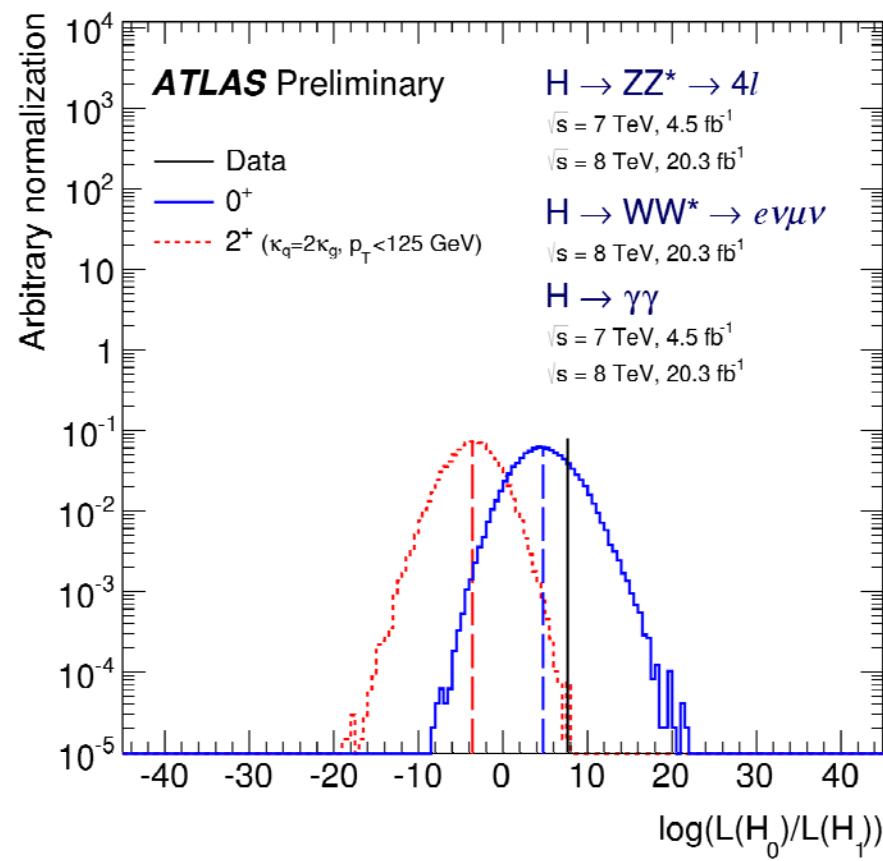

- Use  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow ZZ^*$ , and  $H \rightarrow WW^*$  decays
- Build boosted-decision-trees or matrix-element-discriminants to combine distributions within one channel into one variable

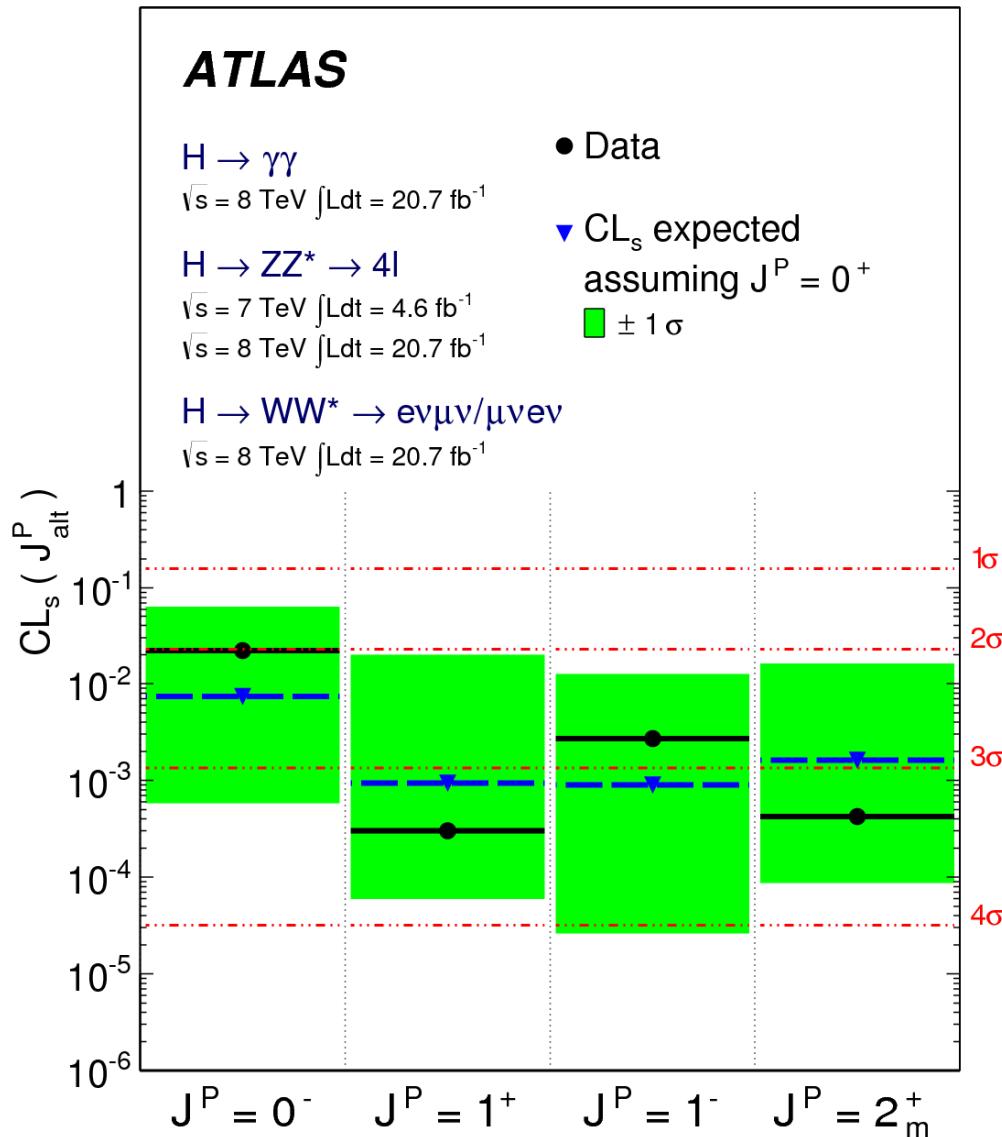

# Spin und CP

## General:

- Build the likelihood ratio for SM and competing hypothesis
- Extract BSM coupling limits

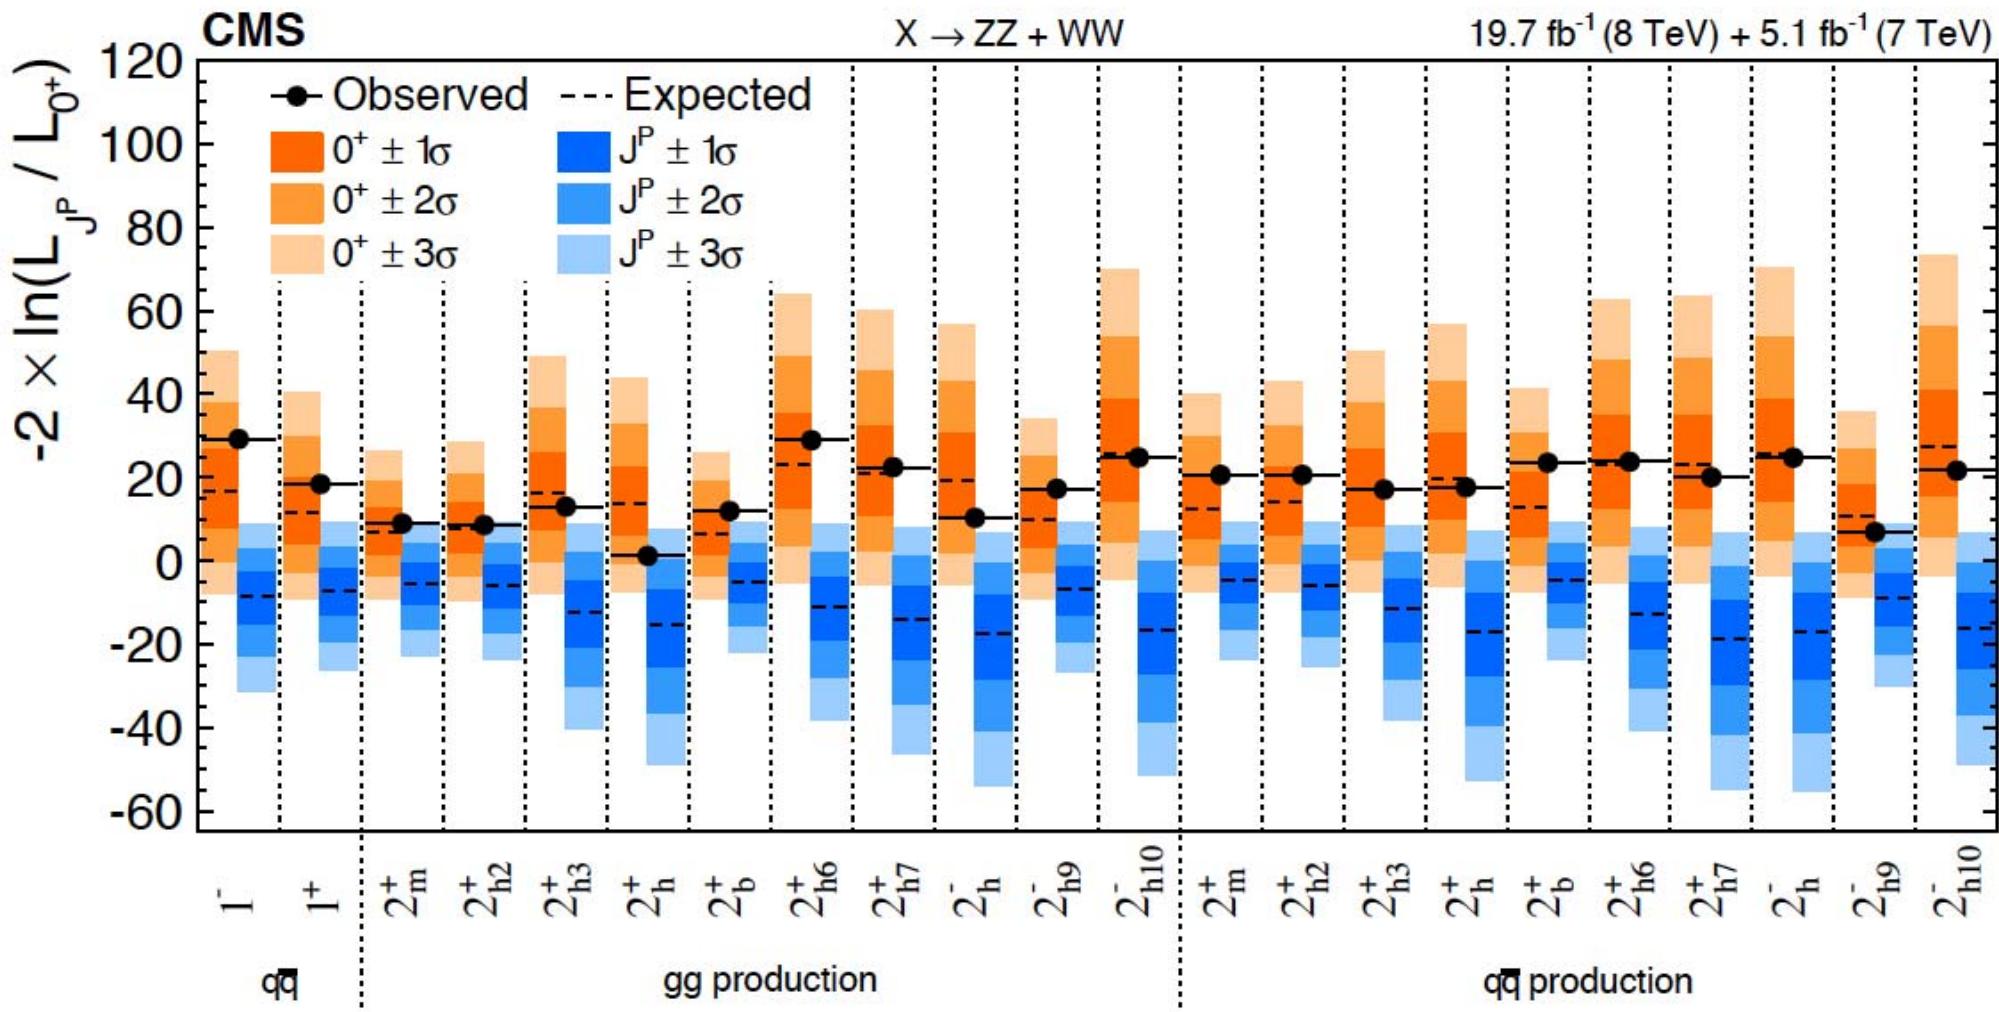

# Spin und CP Summary

- SM  $J^P = 0^+$  favored
- $1^+, 1^-, 2^+$  are disfavored at the  $3\sigma$  level
- $0^-$  excluded at 97.8% CL

# Spin und CP Summary

# Differential cross sections

## General:

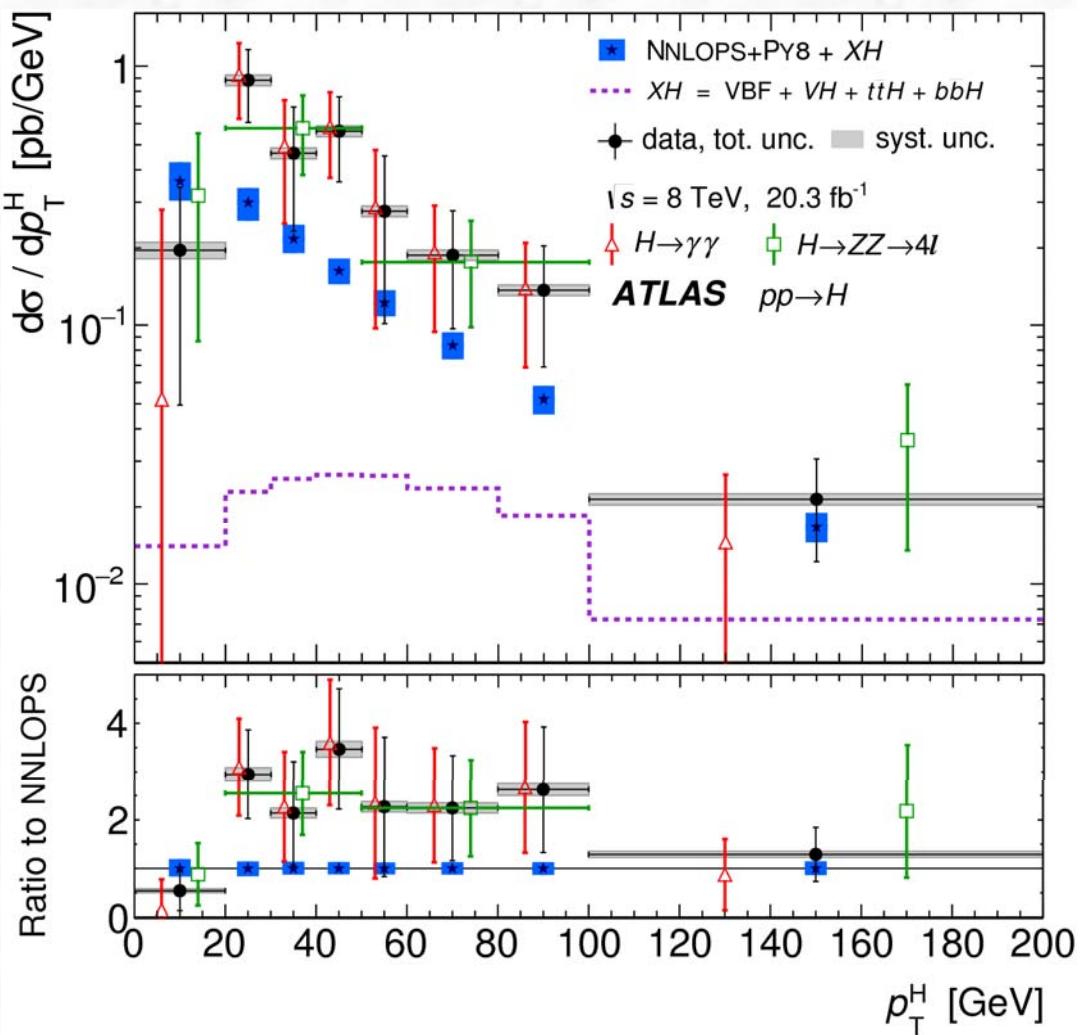

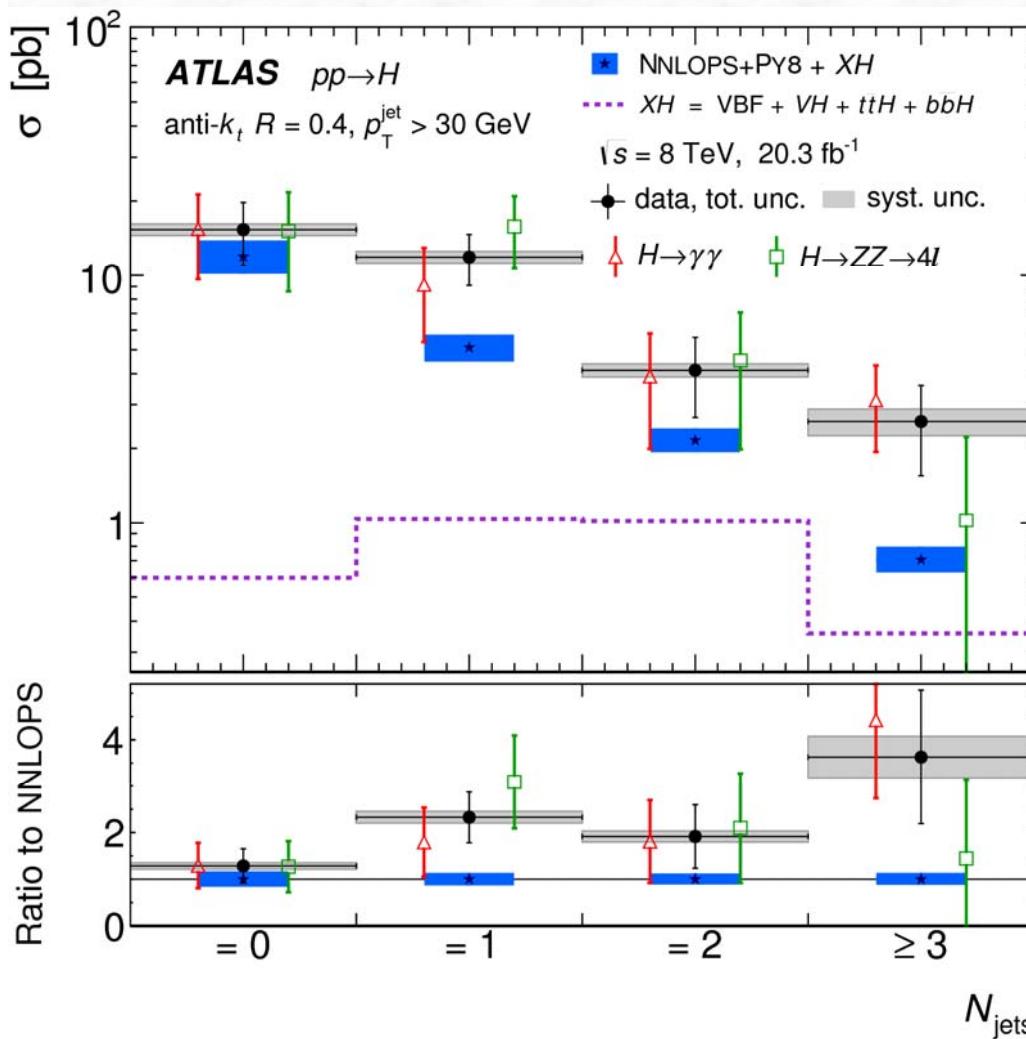

- Unfold measured distributions to true distributions using response matrix from MC
- Needed matrix inversion (with proper uncertainty propagation) non-trivial

## Number of associated jets:

## Higgs-boson $p_T$ :

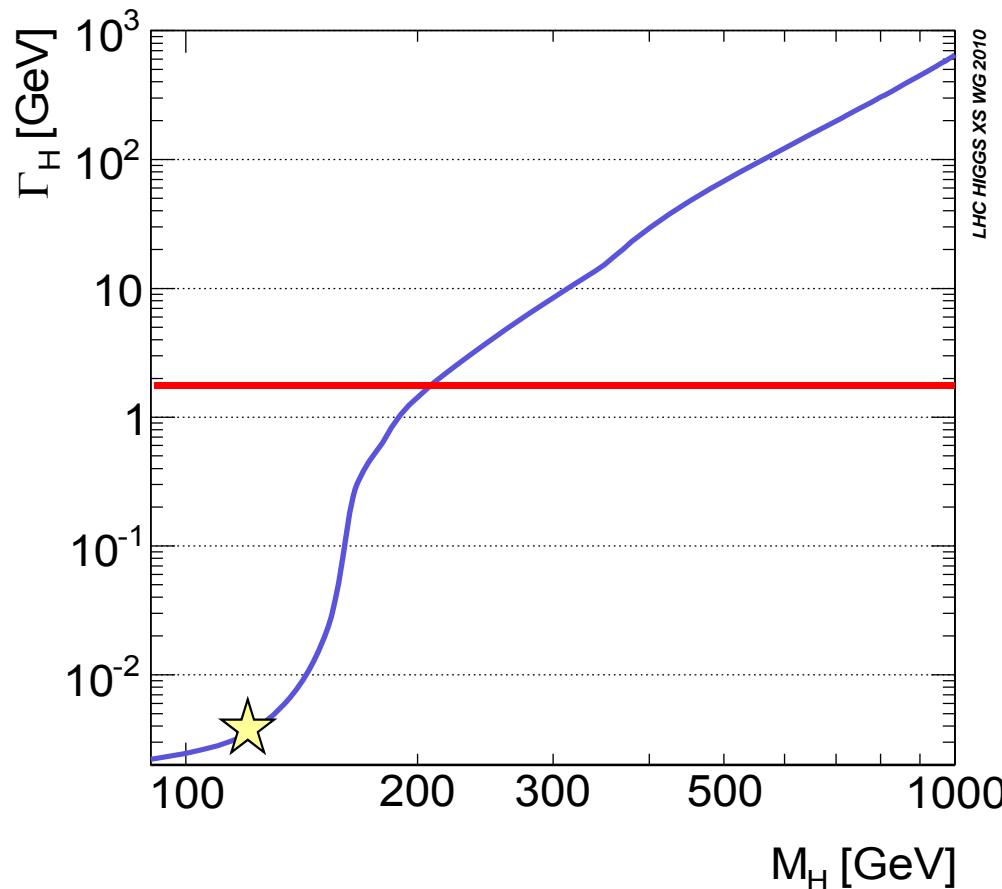

- Test QCD

- Test theoretical modeling

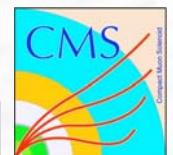

# Higgs boson width

- The Standard Model Higgs boson width is expected to be small:  $\Gamma_H \sim 4 \text{ MeV}$
- Experimental mass resolution in  $H \rightarrow \gamma\gamma$  and  $H \rightarrow ZZ^* \rightarrow 4\ell$  channel  $\sim 1 - 2 \text{ GeV}$   
→ only upper limits can be extracted from the observed mass peaks

EPJ C75 (2015) 5, 212

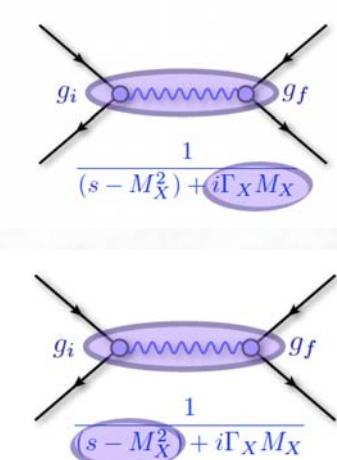

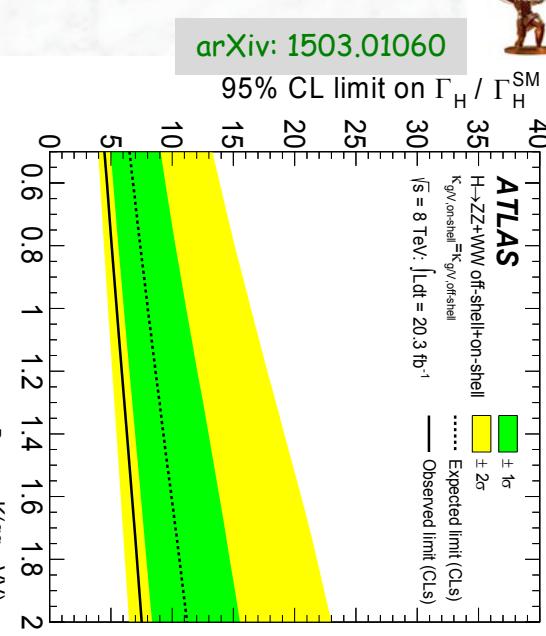

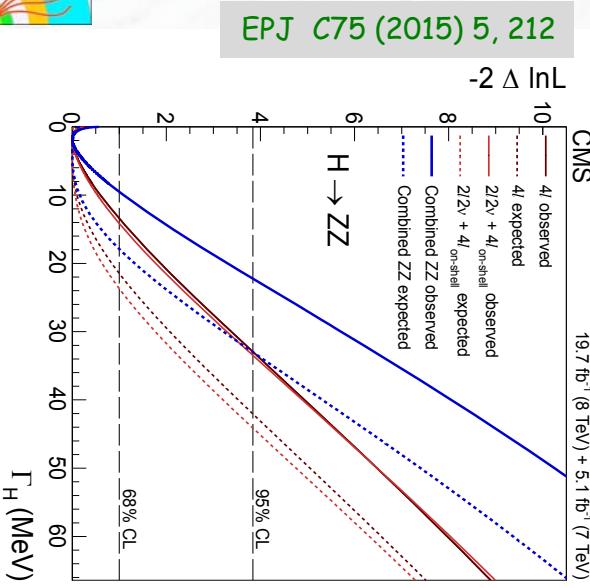

Results: 95% CL limits

$\Gamma_H < 1.7 \text{ GeV}$  (2.3 expected)

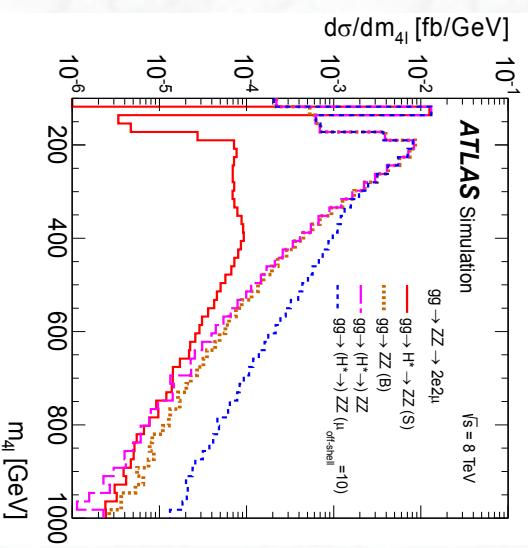

# Indirect constraint on the Higgs boson width from “off-shell cross sections”

- Different sensitivity of on-shell and off-shell cross sections on the Higgs boson width
- However, model dependent: assumes that on-shell and off-shell couplings are the same
- Dependence on K-factors for signal and backgrounds ( $gg \rightarrow VV$ )

$$\sigma_{i \rightarrow X \rightarrow f}^{\text{on}} \sim \frac{g_i^2 g_f^2}{\Gamma_X}$$

$$\sigma_{i \rightarrow X \rightarrow f}^{\text{off}} \sim g_i^2 g_f^2$$

Results: 95% CL limits

CMS:  $\Gamma_H / \Gamma_{\text{SM}} < 5.4$  (= 22 MeV)

ATLAS:  $\Gamma_H / \Gamma_{\text{SM}} < 5.5$  ( $R_B^{H^*} = 1$ )

# Additional Higgs bosons?

Composite  
Higgs bosons

More Higgs bosons

SUSY Higgs

MSSM Higgs bosons

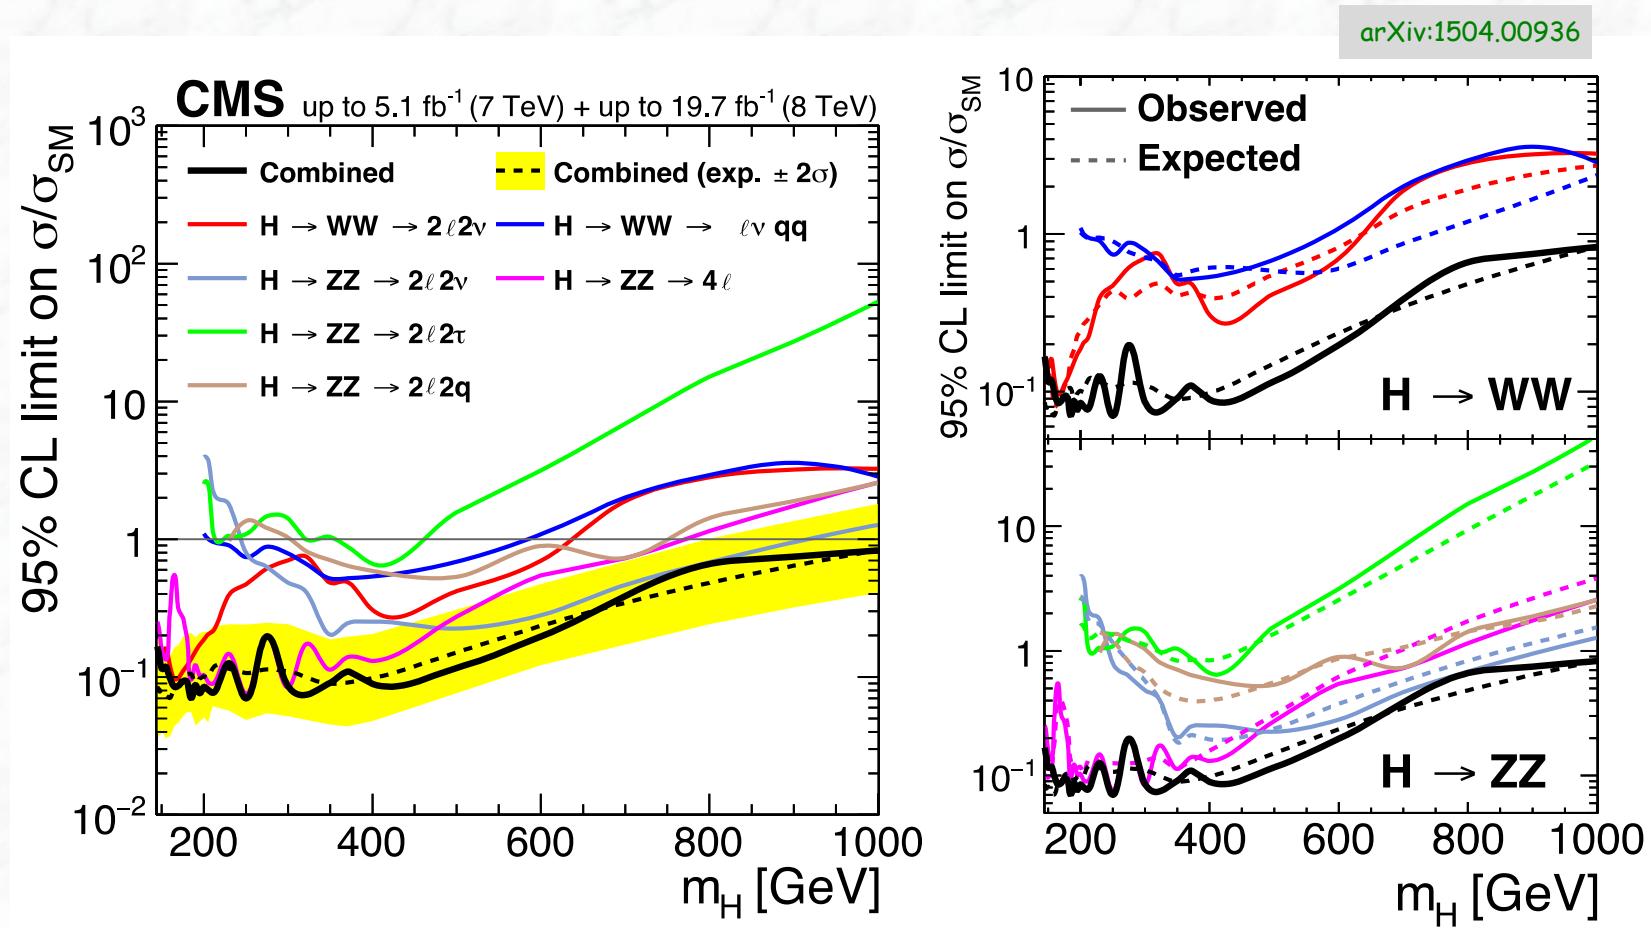

Dark Higgs

Heidi Higgs

No Higgs at the LHC

(ii) Results of a CMS search on additional SM-like Higgs bosons decaying into ZZ and WW

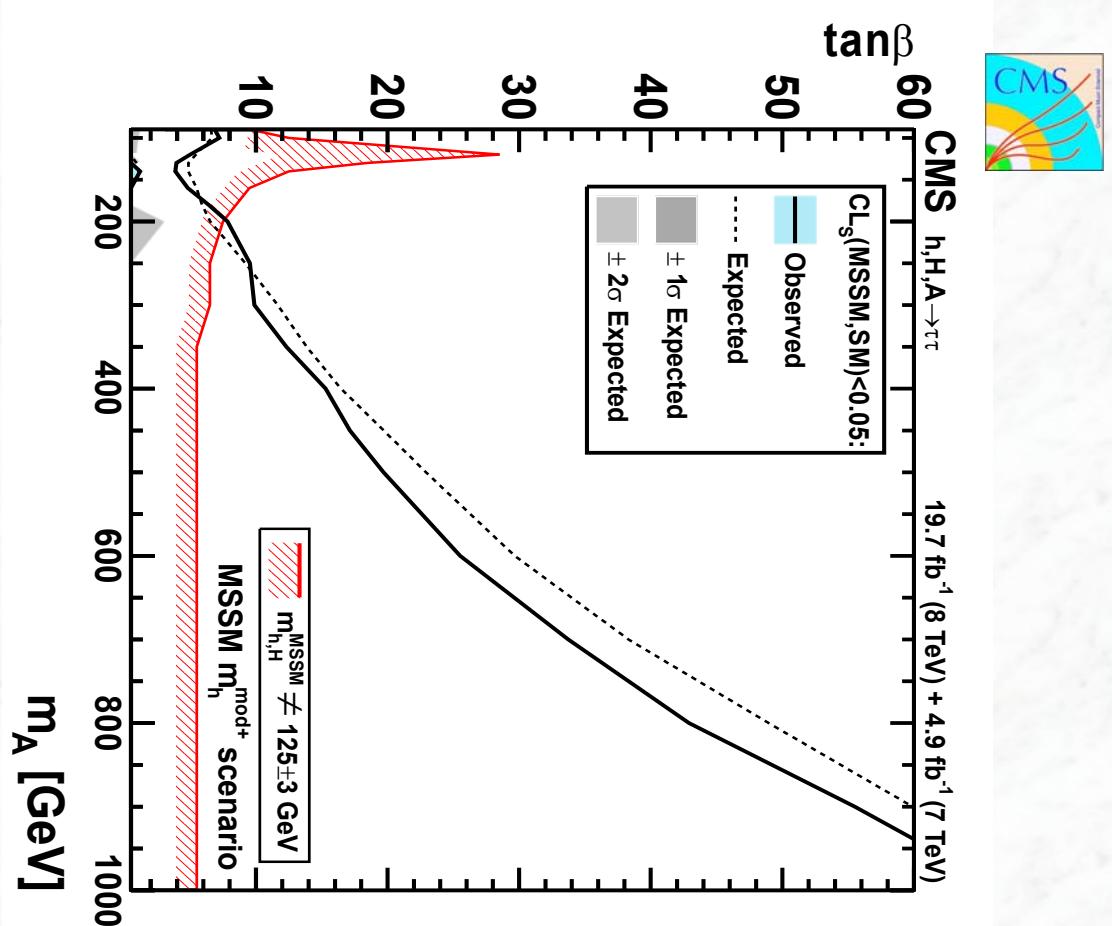

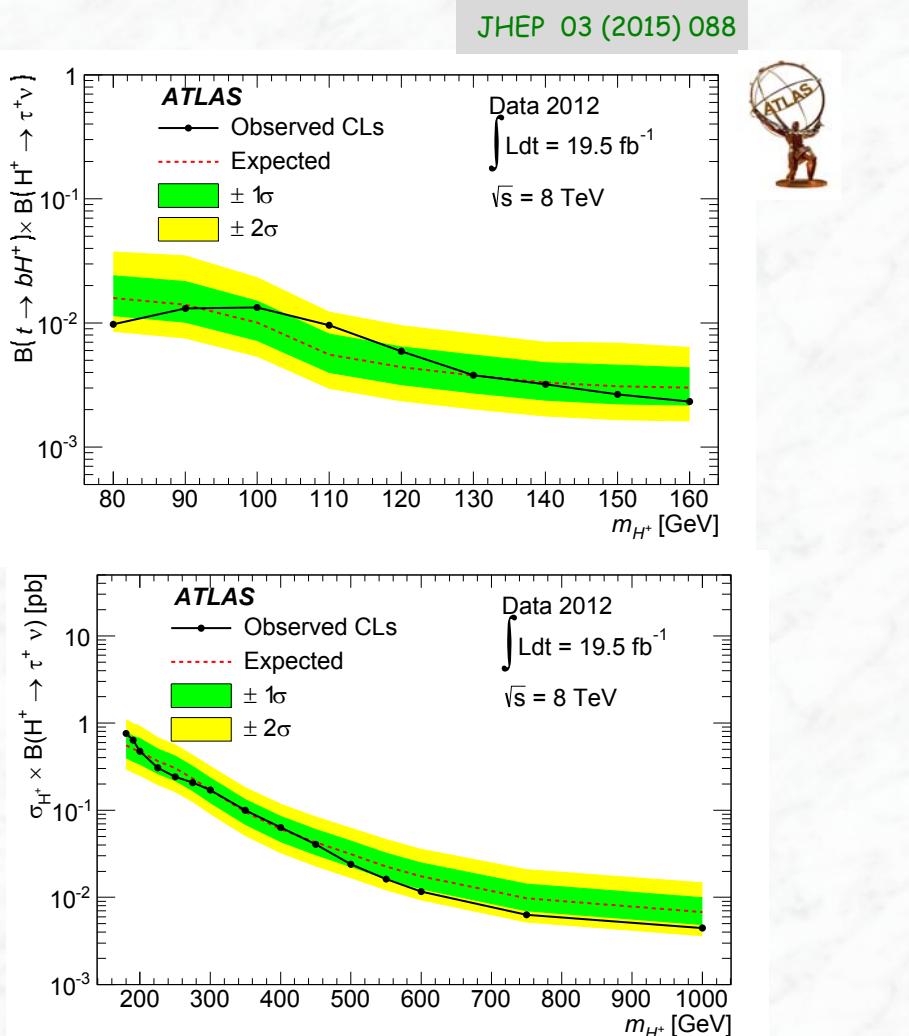

Observed and expected 95% CL limits on the cross section normalised to the SM value for individual channels and their combination

### (iii) Search for charged and heavy neutral MSSM Higgs bosons

Search for  $H^\pm \rightarrow \tau\nu$  decays via  
tt production or tH $^\pm$  associated production

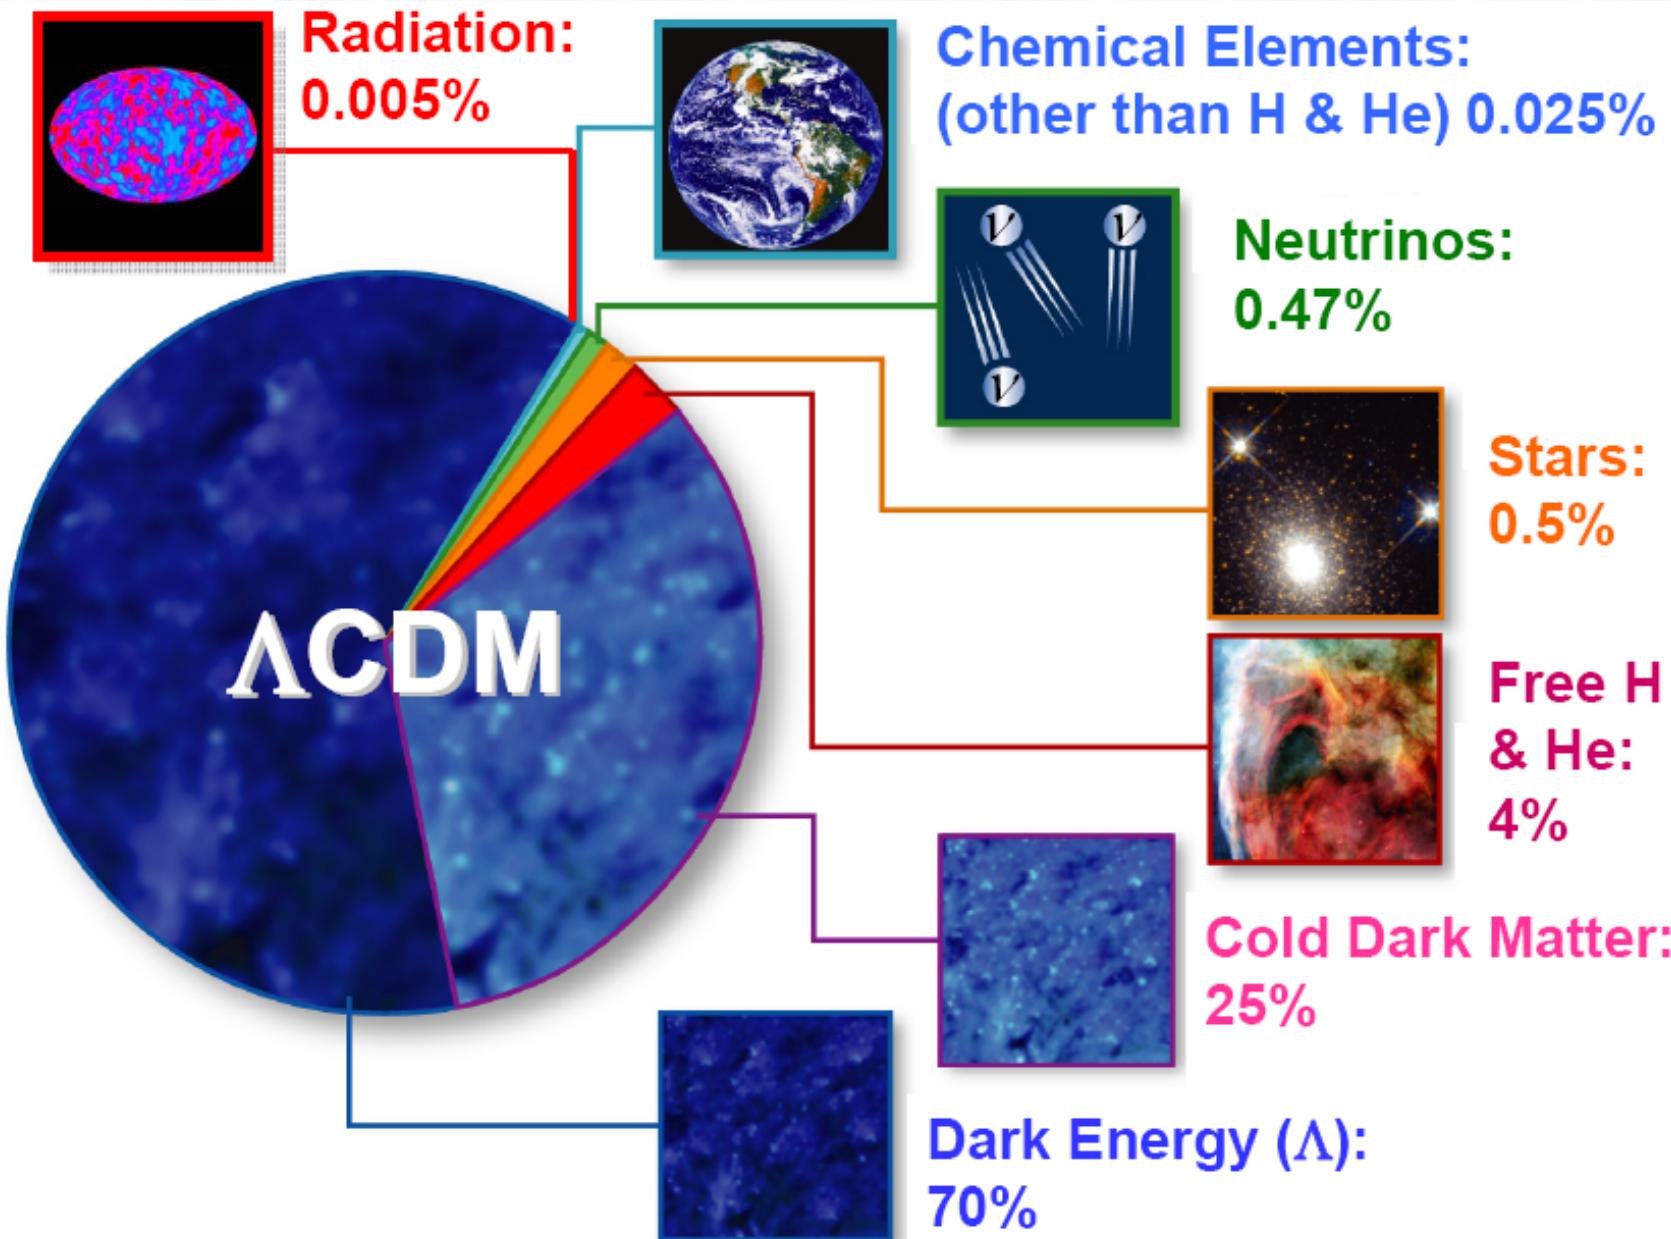

JHEP 10 (2014) 160

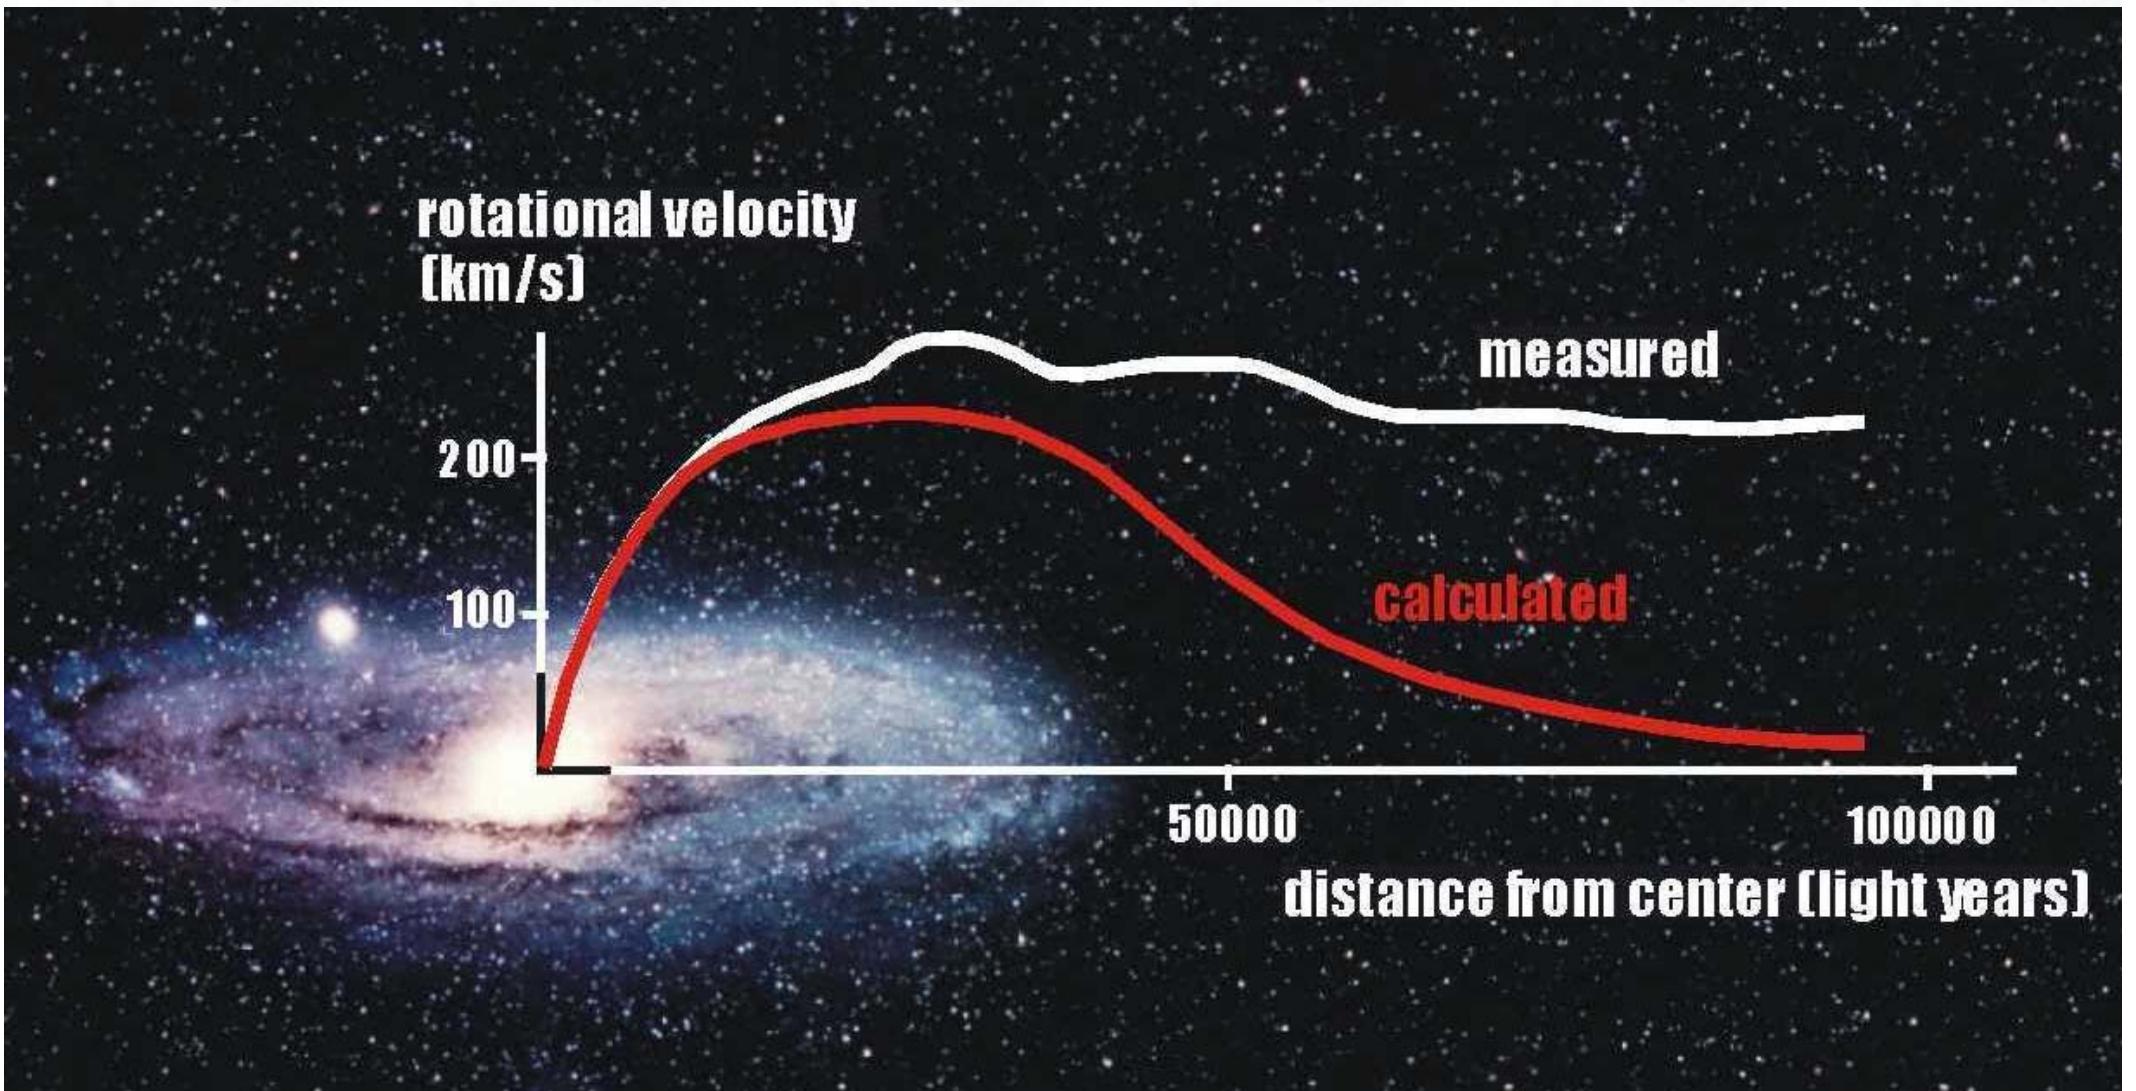

95% CL exclusion limits on branching ratios  
or cross sections times branching ratio

Expected and observed exclusion limits at 95% CL  
in the  $(m_A - \tan \beta)$  parameter plane for the MSSM  
 $m_h^{\text{mod}+}$  benchmark scenario

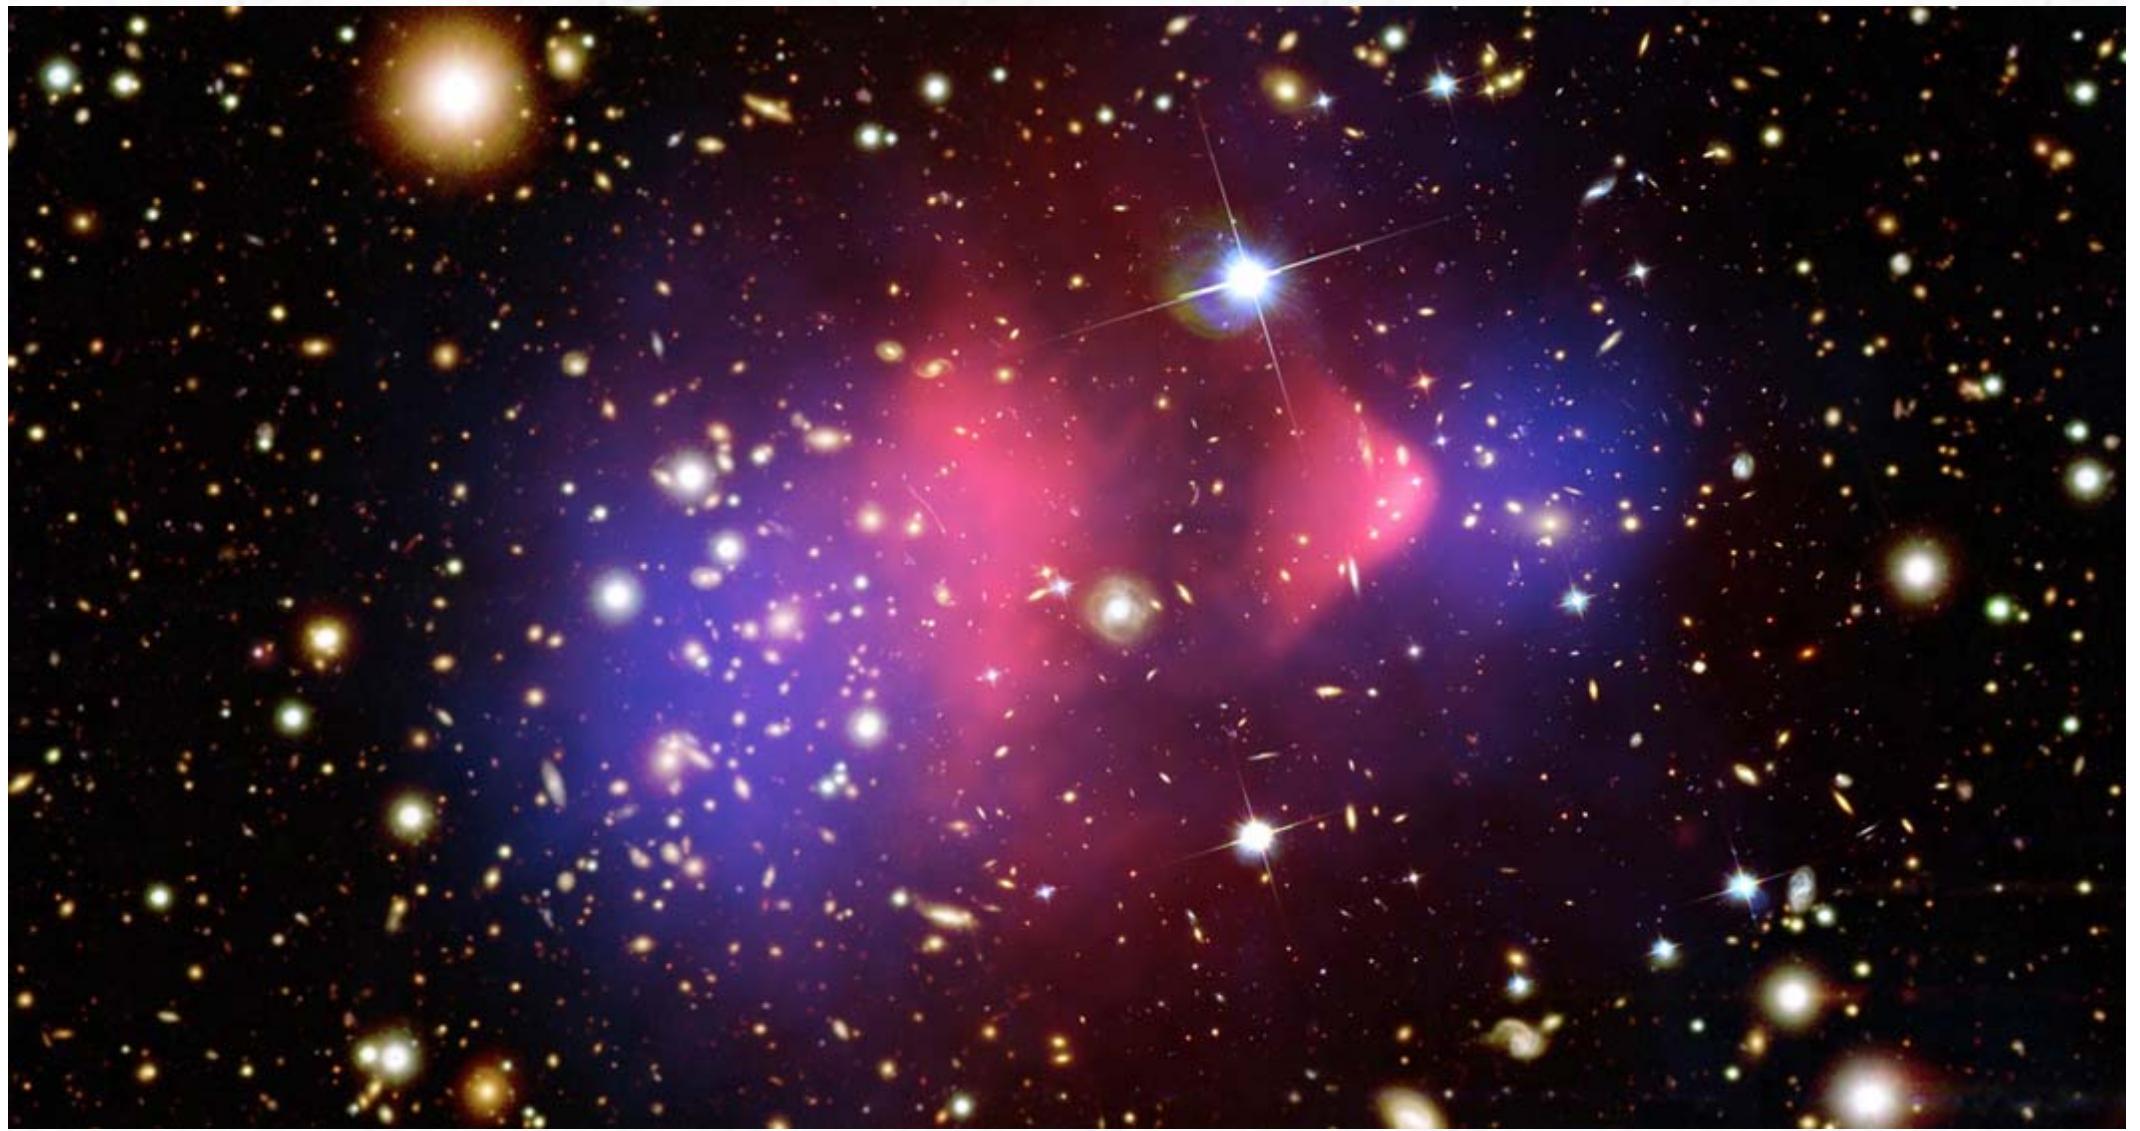

# Mass in our Universe

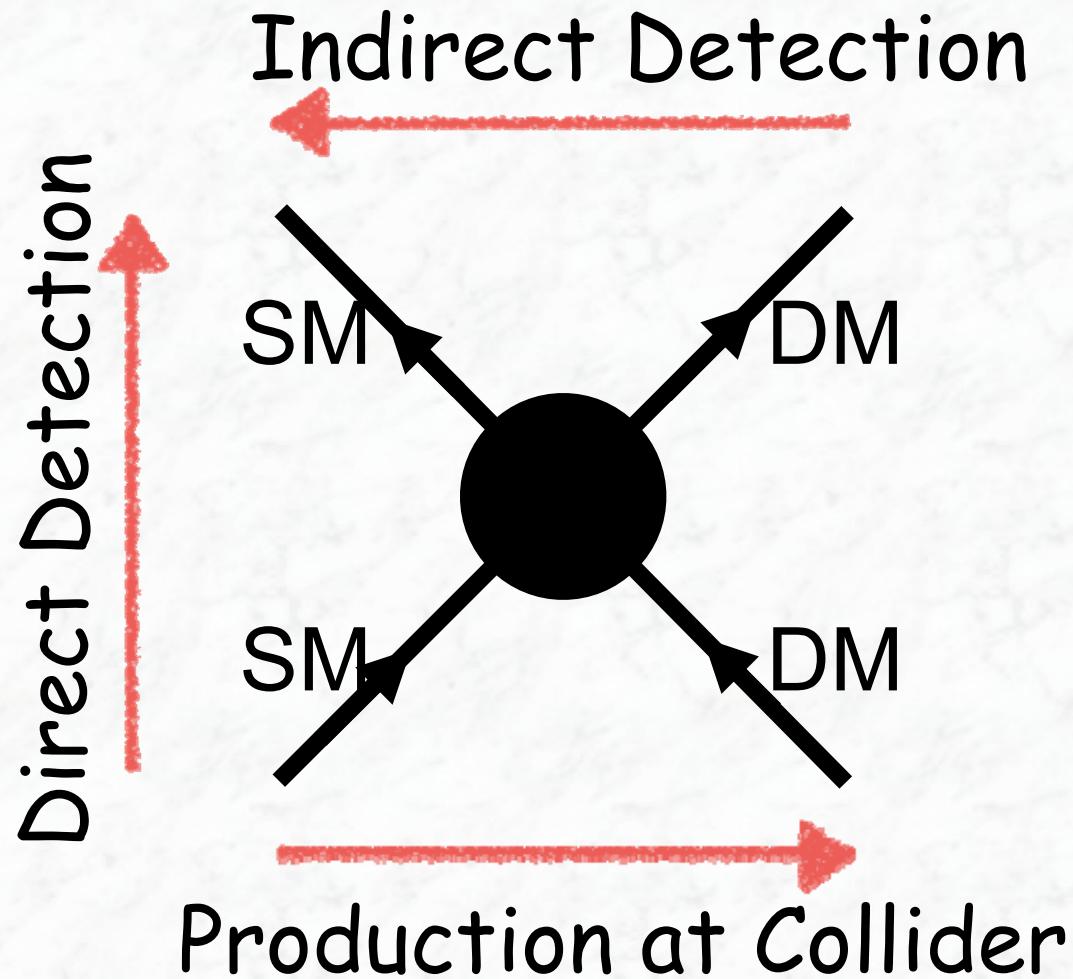

# Dark matter

# Dark Matter

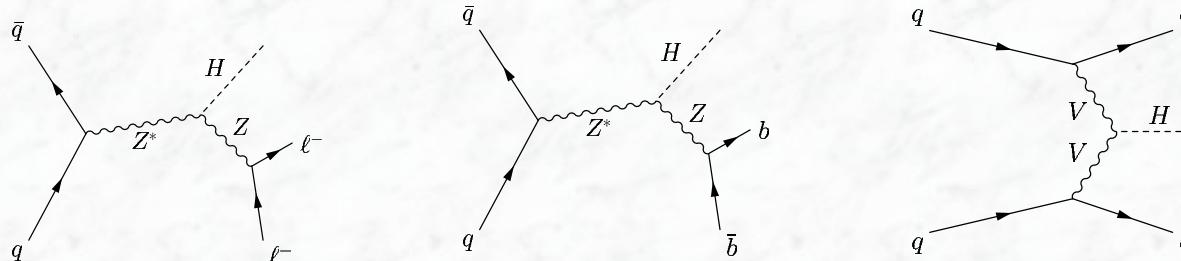

# Dark Matter

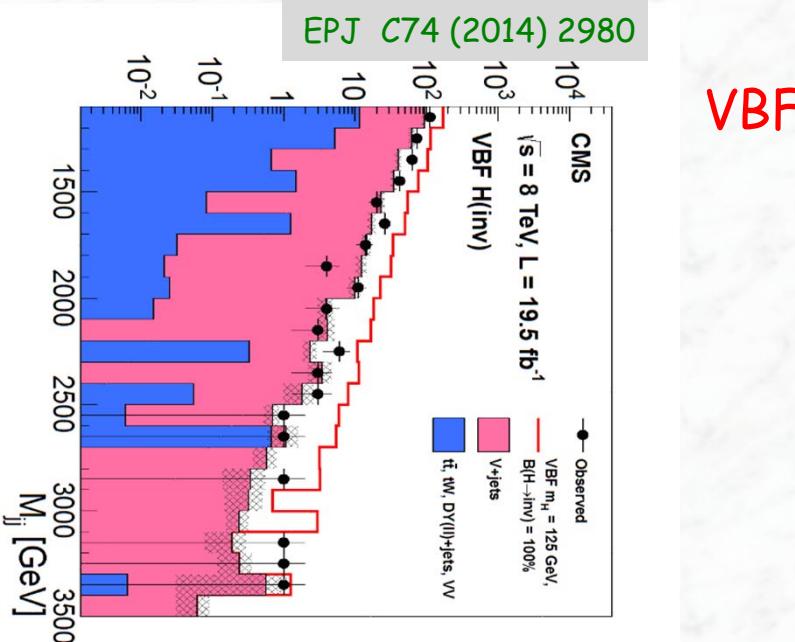

# Search for invisible Higgs boson decays

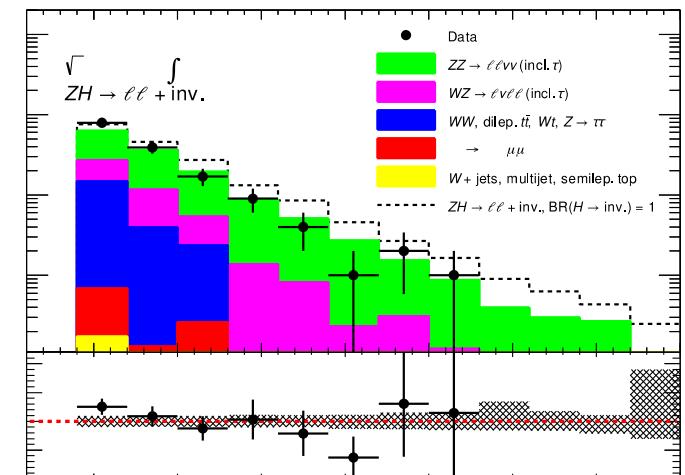

- Some extensions of the Standard Model allow a Higgs boson to decay to stable or long-lived particles

- Search for excess in ZH associated production and VBF production

PRL 112 (2014) 201802

Assuming the ZH and VBF production rates for  $m_H = 125 \text{ GeV}$ :

ATLAS: 95% CL on  $\text{BR}(H \rightarrow \text{inv.}) < 0.75$  (from ZH production)

95% CL on  $\text{BR}(H \rightarrow \text{inv.}) < 0.29$  (from VBF production) [ATLAS-CONF-2015-004]

CMS: 95% CL on  $\text{BR}(H \rightarrow \text{inv.}) < 0.58$  (from ZH + VBF combination)

# Interpretation in Higgs-portal models

-Stable dark matter particles with couplings to the Higgs boson-

- For  $m_\chi < m_H/2$ , limits on invisible branching ratios can be translated to the spin-independent DM-nucleon elastic cross section for scalar, vector and fermionic DM particles
- Higgs-nucleon coupling, model dependent: assume  $0.33^{+0.30}_{-0.07}$  (lattice calculations)
- Within this model, interesting limits for low  $m_\chi$  masses
